Face detection; Face recognition; Haar cascade classifier; Image processing; Occluded faces

Definition

Detection of partially occluded faces in digital images using AdaBoost Haar cascade classifier is a viable technique of face detection if the cascade training procedure is modified.

Introduction

Face detection is one of the more popular applications of object detection in computer vision. The computer uses a series of mathematical algorithms, pattern recognition, and image processing to identify faces from an image or video input. Over the years, the technology of detecting faces has evolved proportional to its usage in various applications. The most known algorithm for face detection was introduced by Viola and Jones in 2001. They proposed a framework that produces real-time face detection by the means of a novel image representation known as integral image and incorporated the Haar basis functions that was used in the general framework of object detection (Papageorgiou et al. 1998) with AdaBoost and implemented it in a cascade structure, creating a boosted cascade of weak Haar-like feature classifiers (Viola and Jones 2001).

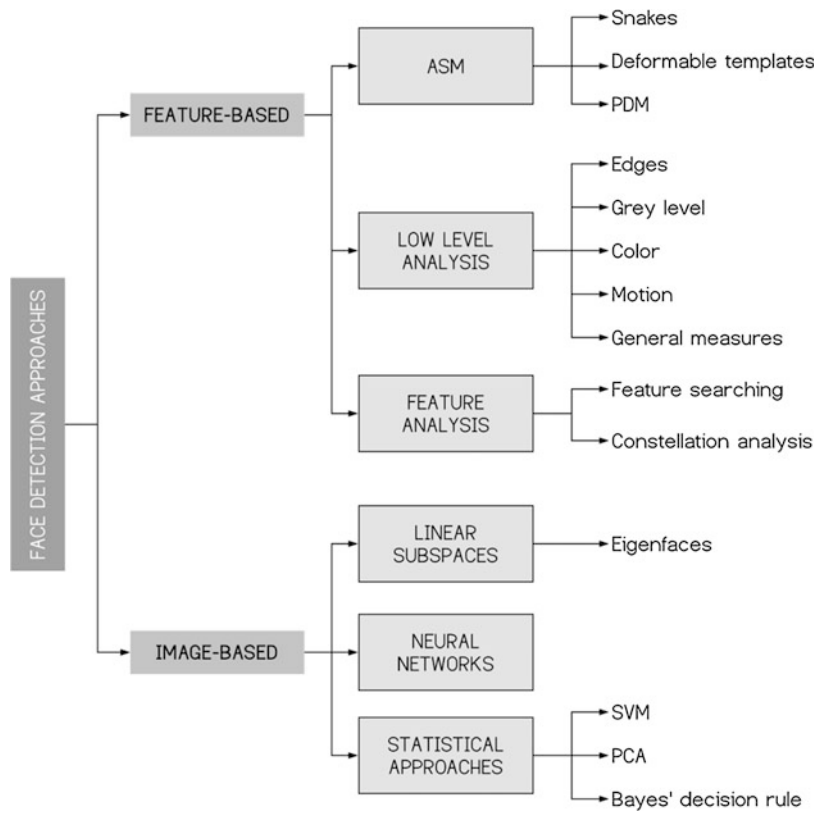
Since the introduction of the Viola-Jones framework, various researchers have adapted the framework and made improvements to the original framework keeping with the advancements of technology. The most recent application of the framework was via GPU architecture and combining Viola-Jones' method with a neural network. The contribution of Viola and Jones is only surpassed by Lienhart and Maydt in 2002 when they extended the set of Haar-like features used in the framework. Their contribution of rotating the Haar-like feature by 45° and also a center-surround feature provided the cascade with more features to compute without increasing the computation time (Lienhart and Maydt 2002).

State-of-the-Art Work

Classification of Face Detection Techniques

Face detection approaches can be grouped into two distinct approaches: feature based and image based. Feature-based approaches in face detection requires the extraction of facial features from an image and comparing it with a knowledge base of face features, whereas image-based approaches attempts to get the best match while comparing training images against testing images (Modi and Macwan 2014). Figure 1 illustrates the classification of face detection algorithms.

The feature-based approaches consist of active shape models (ASMs), low-level analysis, and feature analysis. Active shape models were developed by Tim Cootes and Chris Taylor in 1995, where a shape of an object in the form of a statistical model is used to find the object in a new image by the means of iterative deformation to fit the new object (Cootes et al. 2000). Low-level analysis is a feature-based approach that uses visual features such as edges, gray scale levels, color information, motion, and general measures to differentiate facial features of a face with its surroundings in an image (Singh et al. 2017). Meanwhile, feature analysis refers to the usage of the geometrical facial features to locate faces irrespective of illumination, pose, and angles. There are two methods of implementing feature analysis in face detection, which are feature searching, such as Viola-Jones method and constellation method.



Digital Images Using Heuristic AdaBoost Haar Cascade Classifier Model, Detection of Partially Occluded Faces, Fig. 1 Classification of face detection algorithms

Meanwhile, image-based approaches aim to improve the unpredictability of the various feature-based approaches. The strategy this approach utilizes is treating face detection as a pattern recognition problem, whereby the specific application of face knowledge is steered clear from and the issue is tackled as learning to recognize face patterns from examples (Hjelmås and Low 2001). The fundamental approach of image-based methods relies on training procedures that classify the samples as face and non-face classes. The straightforward approach is illustrated by template matching. Most of the methods rely on an exhaustive search done by a window scanning algorithm in an attempt to detect faces. However, there are various methods under the image-based approach such as linear subspace methods, neural networks, and statistical approaches that are able to accomplish the task of face detection successfully.

Since this entry aims to improve face detection of partially occluded faces using the Viola-Jones method, there are some modifications that have been done on the original algorithm that are worth mentioning. In 2002, the Viola-Jones method was enhanced by using an extended set of Haar-like features which rotates the Haar-like features by 45° that improved the false positive rates (Lienhart and Maydt 2002). The initial Viola-Jones method has gone through various enhancements and modification. Later, a new variant of AdaBoost known as asymmetric AdaBoost was introduced (Viola and Jones 2002). Then another form of boosting was introduced when FloatBoost was used in a detector-pyramid architecture to detect and recognize faces (Zhang et al. 2002). In 2003, researchers introduced a boosting chain to enhance the cascade model for object detection which was later used for face detection (Xiao et al. 2003). A novel variant of Viola-Jones that uses a nested cascade structure for multi-view face detection proved to be successful for detection of faces from various viewpoints (Huang et al. 2004). In 2005, a similar approach as Viola-

Jones was introduced. However, it used joint Haar-like features for classifiers (Mita et al. 2005). It became increasingly important to detect faces that are non-frontal or multi-view faces in images and video. A research put forth the idea of using width-first search (WFS) tree structure to improve the performance of speed and accuracy of the detection by implementing a vector boosting algorithm based on the real AdaBoost algorithm, and a piecewise function with LUT was used to aid with the weak classifiers (Huang et al. 2005).

Other hybridization of the Viola-Jones method includes using color information whereby skin detection is used by computing the skin percentage (Mahmoud et al. 2011). Another popular variation is to combine the Viola-Jones method with a neural network, where the neural network is used to classify faces with non-faces processing stage (Da'san et al. 2015). Additionally, the Viola-Jones method can be integrated with other known methods such as shape constraints (Cristinacce and Cootes 2003), low-level saliency (Cerf et al. 2008), and with corner points using Shi-Tomasi detector (El Kaddouhi et al. 2017). Recent development of the Viola-Jones detector involves implementation via graphics processing unit (GPU), multi-threaded central processing unit (CPU), and field-programmable gate array (FPGA). The proposed usage of FPGA hardware architecture design with AdaBoost face training and detecting algorithm improved the performance of the face detection algorithm (Lai et al. 2007). In 2011, researchers proposed a technique that uses GPU computing to implement a modified Viola-Jones framework (Devrari and Kumar 2011). Moreover, the study done to compare the implementation of the Viola-Jones framework in a single-threaded CPU, a multi-threaded CPU, and a GPU implementation using CUDA shows the GPU implementation to be the fastest (Krpec and Němec 2012).

Application of Face Detection

Over the years, the popularity of face detection has yet to cease. The usage of face detection in the industry has only increased with the age of technology. Face detection now plays an important role in face recognition and biometric authentication. Additionally, face detection is also extensively used in the software embedded in digital cameras. Most digital cameras and cameras on mobile phones use face detection to detect and focus on the faces to reduce blurriness. Meanwhile, social networks and social applications such as Facebook and Snapchat use face detection to further enhance user experience (Rajawat et al. 2017). These application and usage of face detection further motivates researchers to optimize and address the issues faced in face detection as this directly impacts the industrial application of face detection.

Open Issues in Face Detection

The challenges encountered in the field of face detection and recognition in digital images are commonly expressed as A-PIE, which represents aging, poses, illumination, and expression (Mahalingam et al. 2014). Humans are able to identify faces almost instantaneously despite the changes that occur due to aging; however, computers do not have this ability. The difficulty encountered due to aging is still being regarded as a problem as the physical changes of a person over different periods of time can be subjected to external factors such as injuries and cosmetic surgeries. In terms of poses, the degree of head rotation will affect the amount of facial features available for detection. Illumination also plays a part in the detection of faces. If minimum lighting is available in the image, then it becomes a challenge to differentiate the change in pixel value which is required to detect features of a face. Finally, in terms of emotion, the changes in human expression would not be recognized easily if the face detection model is not trained to recognize a variation of emotion, as the general structure of the face changes when a person experiences different emotions. Additionally, partial occlusion poses a problem in face detection as well. Some of the A-PIE challenges can also be considered as a partial occlusion problem as well.

Researchers began noticing that partial occlusion of faces affects the overall detection rate of the algorithm. Most of the face detection techniques work by searching facial features such as mouth, nose, and a set of eyes in images in a joint search. Therefore, occlusions such as sunglasses and scarves hinder the detection of faces which consequently affects the performance of the detection algorithms.

The detection of faces in images are made difficult with the limited visibility of faces due to various factors such as pose variation, poor lighting, and occlusions due to hats, scarfs, hair, and foreign objects. To accurately detect these partially occluded faces in images without using artificial intelligence (AI) requires an approach that does not sacrifice too much in terms of computation time and false positive and negative rates.

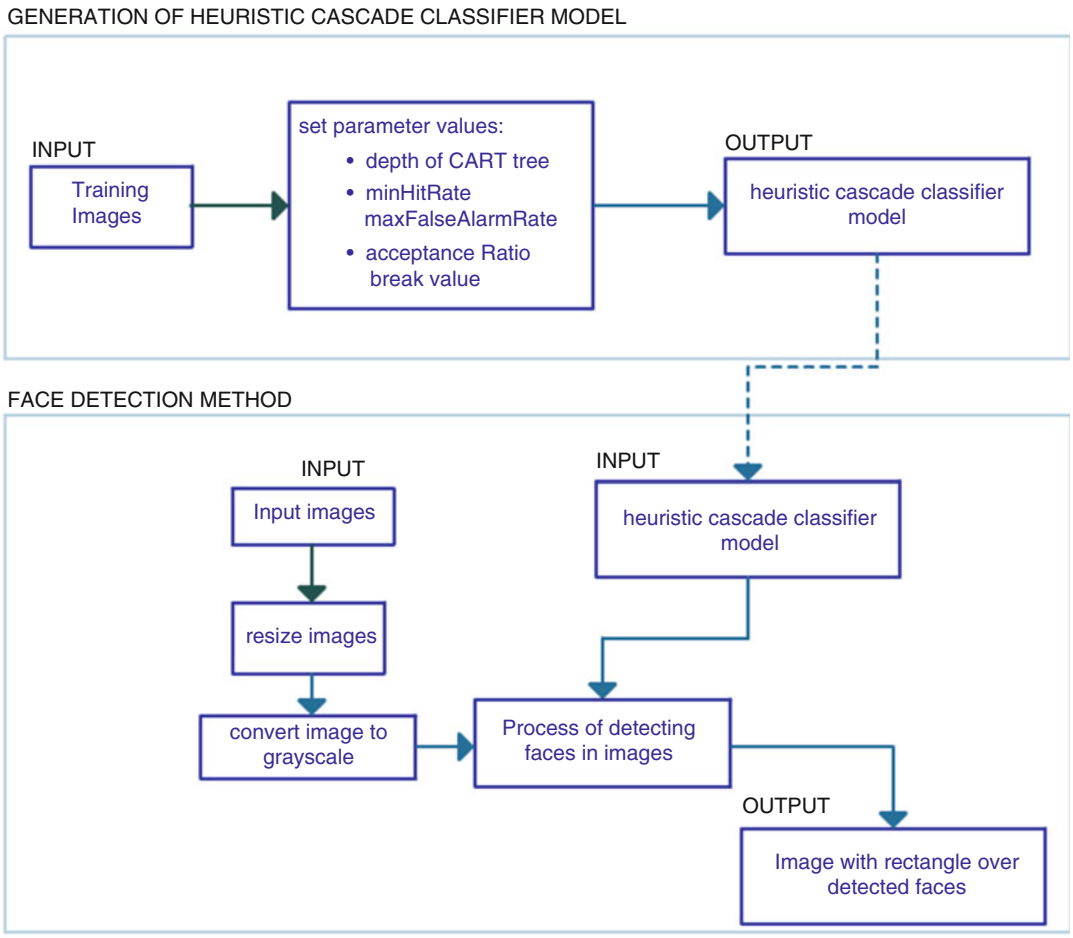
Despite all these problems, the Haar cascade model can be used to improve the detection rates of partially occluded faces with proper calibration. If the model is trained with sufficient images that has a variation of occlusion and A-PIE characteristics, the model will be able to detect faces in said problematic conditions. Additionally, the sensitivity of the Haar cascade classifier model training also influences the rates of detection and false positives that would be given in the face detection.

Heuristic Haar Cascade Classifier Model

A heuristic Haar cascade classifier can be created by setting different training parameters that within the threshold of the Haar cascade classifier model from Lienhart and Maydt. The parameters that influence the detection rates of faces are the depth of the decision tree, minHitRate and maxFalseAlarmRate. These parameters determine the number of features or weak classifiers selected in a particular stage, in addition to the performance of the cascade in terms of detection rates. Moreover, minHitRate and maxFalseAlarmRate also influence the value of the acceptance ratio break value. Once the acceptance ratio break value is achieved, the heuristic cascade model is created; otherwise, a new stage of cascade is added when the maxFalseAlarmRate is reached. The value of the boosting parameters will affect the detection rates of partially occluded faces in images. The integration of optimal tree depth value and boosting parameter values in the cascade training will create a heuristically boosted cascade model. The heuristically boosted cascade classifier model is then used in the architecture of the any feature-based approach of face detection in order to detect partially occluded faces in images.

In order to achieve the best results of face detection, the input image has to go through some preprocessing steps, which are resizing and converting the color space from RGB to grayscale. These two steps are taken to ensure that the best experimental results are obtained for the detection of partially occluded faces in images. Since grayscale images are used to train the cascade, therefore, when executing the face detection algorithm, it is best to use grayscale images. Furthermore, the computation time of a grayscale image is much faster compared to an image that uses three channels. The dimensions of width and height used in the training of the model are usually quite small. Hence, to accommodate this, the input image has to be resized to be twice as small as the original image. Then the trained cascade model is used to detect faces in the image. The detection process involves a subwindow sliding over the preprocessed input image in various scales using the cascade model to evaluate the probability of the sub-window containing a face. In the output, the detected faces or objects in the image have rectangles drawn over them. Figure 2 illustrates the flow of training the heuristic cascade classifier model and the detection of faces in images.

The effectiveness of the heuristic cascade classifier model can be tested using ROC curves, confusion matrix, and comparison tests. The ROC curve is used to analyze the accuracy of the model whereby it can be inferred that the closer the curve is to the top left corner of the graph, the more accurate the cascade model. From the confusion matrix, the F1 score can be calculated. This score is the ratio between accuracy and precision. The Haar cascade classifier models tested for the detection of partially occluded faces needs to have a balanced result between accuracy and precision due to the nature of the



Digital Images Using Heuristic AdaBoost Haar Cascade Classifier Model, Detection of Partially Occluded Faces, Fig. 2 Method of Implementation

features available. For the detection of partially occluded faces in images, one of the factors that would influence the efficiency of the classifier model is the depth of the CART tree. The ideal tree depth would ensure that sufficient feature information is preserved in to enable quick detection without underfitting the CART tree. However, having a high value of tree depth would not be ideal in the case of detecting partially occluded faces in images as a lot of facial features would be discarded due to overfitting the tree. Additionally, the detection rates of a CART tree with a low tree depth will end up taking too much time as it would have to loop through more feature information from the tree.

Figure 3 shows the result of three sample images being tested with three different Haar cascade classifier models which are Haar_frontalface_default, Haar_frontal_face_alt, which are classifier models by Lienhart and Maydt, and a heuristic Haar cascade classifier model trained to detect partially occluded faces.

From Fig. 3, it can be observed that the heuristic cascade works better in detecting partially occluded faces where it was able to recognize facial features under less favorable conditions.

Table 1 shows the confusion matrix analysis preformed to test the accuracy and sensitivity of the cascade classifier models.

Digital Images Using Heuristic AdaBoost Haar Cascade Classifier Model, Detection of Partially Occluded Faces, Fig. 3 Sample images: (**a**) heuristic Haar cascade classifier model; (**b**) Haar_frontalface_default; (**c**) Haar_frontal_face_alt

Digital Images Using Heuristic AdaBoost Haar Cascade Classifier Model, Detection of Partially Occluded Faces, Table 1 Confusion matrix analysis

	Heuristic cascade	Haar_frontalface_default	Haar_frontalface_alt
Accuracy	0.6525	0.5290	0.4843
Recall	0.6945	0.5336	0.5199
Precision	0.8683	0.9839	0.8759
F1 score	0.7717	0.6919	0.6525

The heuristic cascade classifier model is trained with using images that have various levels and types of occlusion. Additionally, the training parameter values are calibrated to enhance the detection of partially occluded faces. The accuracy and true positive rate or recall of the heuristic cascade classifier model is much higher compared to both the other cascade models. However, the precision of Haar_frontalface_default and Haar_frontalface_alt is much better than the heuristic cascade classifier model. Despite this, the ratio of sensitivity and specificity of the heuristic cascade classifier model is 10.9% and 16.7% better compared to the other two cascade classifier models Haar_frontalface_default and Haar_frontalface_alt, respectively. This means that the heuristic cascade classifier model is superior in detecting partially occluded faces when compared to the other two cascade classifier models provided by Lienhart and Maydt.

Additionally, by visually comparing the detection of each cascade model, it is observed that the

heuristic cascade classifier model performs better than the other two classifier models in detecting partially occluded faces in digital images. The heuristic cascade classifier model outperforms the Haar_frontalface_default and Haar_frontal_face_alt classifier models contributed by Lienhart and Maydt by 23.66% and 21.7%, respectively, in detecting partially occluded faces in images.

Conclusion

A heuristically trained Haar cascade classifier model can be used in order to detect partially occluded faces in digital images. By training the Haar cascade classifier model with various levels and types of occlusion, it increases the probability of detecting partially occluded faces in images. During the training phase, several training parameters can be heuristically determined in order to further enhance the detection of partially occluded faces in images.

Disney Toontown Online, a Massively Multiplayer Online Role-Playing Game

Newton Lee
Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
Vincennes University, Vincennes, IN, USA

Synonyms

Action adventure game; MMORPG; Multiplayer game

Definitions

MMORPG = Massive multiplayer online role-playing game is a multiplayer game designed to be played online simultaneously by a large number of players.

Multiplayer game = a game that is designed for multiplayer mode where two or more players are expected throughout the entire gameplay.

Action adventure game = a game that combines core elements from both action game and adventure game genres.

Introduction

Disney Toontown Online was a massively multiplayer online role-playing game (MMORPG) developed by The Walt Disney Company (Madej and Lee 2020). It was first released in 2003 and it allowed players to create their own cartoon avatars called "Toons" and explore a virtual world filled with various activities, quests, and challenges.

In Toontown Online, players could battle against comical villains called the "Cogs" who were trying to take over the world of Toontown. Players could team up with other Toons to defeat the Cogs using a variety of gag weapons such as cream pies, squirt guns, and anvils.

Toontown Online was popular among both children and adults due to its colorful graphics, fun gameplay, and social features. It was known for its focus on teamwork and collaboration, encouraging players to work together to complete quests and defeat the Cogs. The game was shut down in 2013 after a successful ten-year run, but it has since been revived by a group of fans who have created their own version called Toontown Rewritten.

A Different MMORPG

Toontown Online is based not in the traditional quest, fantasy, or science fiction themes of most MMORPGs. Instead, Toontown is a whimsical virtual world in which Toons, cartoon characters of the 1940s variety, inhabit six neighborhoods. The neighborhoods are happy, colorful places and each is associated with a classic Disney character. As an element of conflict in the game, mean Cogs, out-of-control business robots, have come to town and are ruining this happy environment by making it a black and white city of skyscrapers and businesses. The game enlists players to become Toons to save the town. Toons talk with each other through word balloons and take their world back by using traditional cartoon practical jokes and slapstick comedy such as cream pies, seltzer bottles, and whistle blowers against the Cogs, who have no sense of humor and cannot take a joke. The game was designed mainly for children (7 and up), but adults also enjoyed Toontown's nostalgic elements, humor, and game play.

Toontown's Backstory

Toontown's story begins on the outskirts of the place cartoon characters call "home." On this day, world-famous billionaire Scrooge McDuck decides to pay a visit to his favorite employee, eccentric inventor Gyro Gearloose.

Gyro has posted a warning sign on his laboratory door that says "KEEP OUT." Scrooge ignores it, opens the door, and calls out "Gyro?" He walks pass a vast array of laboratory equipment, test tubes, and microscopes. Gyro is nowhere to be found. "I wonder where Gyro could be?" thinks Scrooge. In the back of Gyro's laboratory, Scrooge is stunned by what he sees and cries out, "Sufferin' catfish! A g-g-giant robot!"

Scrooge then thinks to himself, "Hmm... A giant robot... Perfect... Why, a thing like this could be a really big help to the citizens of Toontown... And make me a big pile of money!"

However, Gyro has left a huge note on the robot that says "DO NOT TOUCH!" Scrooge is upset. "Do not touch?" he thinks, "Phooey! That can't mean me! After all, I paid for it.... Let's get my investment up and running!"

Scrooge proceeds to connect the broken wires – the blue one to the red one. The giant robot instantly comes to life!

"All systems ready!" says the giant robot in a deep voice. Scrooge begins to worry, "Great heavens to Betsy! What have I done?"

His fears are fulfilled as the giant robot stomps toward the control panel, pushes the red buttons, pulls the lever, and manufactures hundreds upon hundreds of evil robots called Cogs. They come in various sizes, shapes, and abilities to inflict evils in Toontown. Scrooge panics, "Oh my heavenly days! This can't be good...".

The story ends with Gyro's invention running amok. Scrooge has placed himself and all of Toontown in danger. Can anyone stop this army of robots? "Toontown needs your help now!"

Becoming a Toon

To save Toontown from the evil Cogs, the player has to become a Toon. Each account holder can create up to six Toons in the virtual world. A menu of characteristics such as height, weight, color, and fashion style are available to make each Toon an individual character that reflects a player's preferences.

Naming characters in games has often been abused, and it is almost impossible to create a filter that would prevent players from using inappropriate names that might be offensive to some of the audience. Instead of relying on an automated "naughty list" filter, Toontown Online employs a name generator that gives a player millions of possible combinations based on a choice of title, first name, and last name from a suggested list. The generated list provides names that are in keeping with the humorous nature of Toontown. To avoid the problem of inappropriate names, players are offered a list of titles and first and last names from which to choose their avatar's name. If the player chooses, they may enter their own name, which goes through client and server-side filters and is reviewed by a Disney customer representative before acceptance.

Once a player has made and named her/his own Toon, they are ready to enter Toontown and meet and play with other Toons. In keeping with the positive, upbeat tone of the site, if Toons join on a special day such as New Year's Day, they are greeted in the playground with a display of fireworks.

Safe and Friendly Socializing

Toontown encourages socializing and incorporated in the game are features that facilitate socialization that is friendly, safe, and fun. Communicating through chat is a necessity in a multiplayer game; in most MMORPGs it is unrestricted. To protect kid's privacy and ensure online safety, Toontown Online features SpeedChat, a menu-based chat system that provided safe player-to-player text interaction. Kids choose what they want to say from an extensive set of preselected context-sensitive words and phrases that automatically adapt to the player's objectives and status in the game. The set menus eliminate game jargon that may not be understandable by new players and helps novice typists who may have difficulty with grammar and spelling. A particular feature is that the phrases are friendly and encourage engagement and cooperation between players.

SpeedChat is sufficient to convey a player's feelings (e.g., happy or sad) and simple thoughts (e.g., follow me, let's play a game) that are enough to play the Toontown game without hindrance. The friendly nature of the word sets helped to overcome shy players' inhibitions. Overall, the lack of open chat helped the players focus more on the gaming tasks at hand rather than spending time on chitchatting and digression.

Open chat is available in Toontown between "true friends." True Friends are those who are friends in actual life and may want to chat more extensively when playing online. To activate open chat between two Toons, a randomly generated secret password that is valid for only 48 h is given to each of them. Friends share their secret password over the phone, via email, or instant messaging; each friend must then enter the correct password in Toontown before it expires. True Friend chat is filtered for inappropriate language and the chat is incomprehensible to other Toons.

In addition to making chatting safe as well as friendly and engaging, Toontown offers many shared activities to help with making friends and becoming a part of the community: there are mini games to play, opportunities to go fishing, and ongoing Cog battles to join. Socializing is encouraged by the simple way in which newbies (newer players) can join play: They could hop on a trolley car and meet other players going to a game or simply walk up to a battle that may be in progress and be instantly included without any chat. Elders (more experienced players) are rewarded when they help out a newbie in battle against the Cogs; because the rewards received in a game are proportional to the contribution made, elders are not penalized in battle when a newbie joins. This positive approach facilitates newer players' inclusion in the gaming community.

Other features were included to make Toontown a friendly environment: Portable holes

allowed players to teleport immediately to wherever their friends are located, there is no player-to-player battling or any opportunity to steal or hoard items, and, instead of getting hurt or dying, Toons become sad and go back to the playground to become happy again.

Collecting and Cooperating to Save Toontown

Toontown Online offers many mini games for the players to win the "jelly beans" necessary to make purchases of cartoon weapons to fight the evil robots. Jellybeans are the main components in the game's system of barter.

Some of the popular mini games are maze, tag, memory, treasure dive, slingshot, ring, cannon, jungle vine, and tug-o-war. Most of these games are action adventure in nature to keep the adrenaline flowing and maintain a quicker pace in the overall mood of Toontown. Although most of the mini games are competitive, there is no "winner takes all" mentality. If the player exerts some amount of effort, chances are he/she will win some jellybeans, although perhaps not as many as the winner. For newbies there is a series of training tasks to follow to learn how to win jellybeans, explore the virtual world, and destroy the evil robots. Toons battled Cogs with cooperation and comic rather than violent action.

Cogs have different names such as Pencil Pusher, or Tightwad, according to their different abilities, and they are classified into different levels according to their power. Regardless of their abilities, high-level Cogs are more dangerous than low-level robots. It often takes simultaneous actions from a team of Toons to destroy a high-level Cog. When fighting against the evil robots or Cogs, Toons need to cooperate with each other.

Once all the Cogs have been evicted from a building and eliminated, the ugly grey building is magically transformed into a happy place with bright vibrant colors. The team of Toons that accomplished this task is rewarded by having each player's Toon name displayed on the wall of fame inside the building. In addition, the top Toons and their accomplishments are announced in The Toontown Online Times daily newspaper.

Toontown Innovation and Panda3D

Toontown Online was designed as "a safe social game that was simple to learn yet challenging to master" (Mine et al. 2003). When released, Toontown proved to be innovative in many ways:

- It provided a safe online environment for children thanks to the Toon name generator, SpeedChat, and True Friends.
- It encouraged both competitiveness (in the mini games) and cooperation (in fighting against evil). There is no "winner takes all" mentality even in a competitive mini game.
- It minimized violence in the gameplay through the use of cartoon slapstick weapons such as cream pies and seltzer bottles instead of guns and swords, and by using robots that are mechanical rather than humans. Because Toons never die, but rather become sad, issues of physical pain, blood, and death didn't arise as they do in adult MMORPGs.

Toontown Online was built on an open-source cross-platform Panda3D game engine created by The Walt Disney Company. Panda stands for Platform Agnostic Networked Display Architecture which provides the portability and flexibility for Toontown to run on any operating system. Built on an efficient low-level C++ engine, Panda3D expressive scene graph architecture gave designers tools for creating diverse and dynamic worlds for Toons to inhabit while its interpreted scripting language gave programmers flexibility to prototype software rapidly and debug game logic quickly.

Public Reception

Although Toontown Online was designed as a nonviolent game alternative for kids aged 7–12, adults enjoyed the game as much as kids did, making Toontown Online family entertainment similar to a Disney theme park where kids and

parents have fun together. The monthly subscription model with reduced rates for longer memberships proved acceptable to the audience and profitable for the company. A basic level of play is available free on the site so anyone interested can make a Toon avatar, enjoy walking about, and play a mini game or two to see if they like the environment. In addition to the online subscription plans, prepaid subscription cards (one or more months) were made available at retail outlets to allow sampling of premium content.

Toontown Online quickly gained enormous popularity with a high retention rate after the initial free three-day trial. In mid-2005, Toontown had nearly 10,000 people playing simultaneously during the busiest times. In May 2007, independent Internet research firm Comscore estimated Toontown Online had nearly 1.2 million users. Disney also produced versions of Toontown Online for the UK, France, Spain, Japan, Southeast Asia, and Brazil.

Distributed Simulation and Games

Jouni Ikonen
Software engineering, Lappeenranta University of Technology, Lappeenranta, Finland

Synonyms

Distributed multiplayer game, Simulation, Synchronization

Definition

Distributed game simulation is a single simulation, which has been distributed over multiple processors and interconnected via a network. The game entities are synchronized in a manner, which try to ensure that the game is playable and fair, despite network latencies.

Introduction

Many computer games present dynamically modelled game environments, which are dynamic in the sense that they change over time. Changes to the environment are typically initiated by events, which can be created by users (e.g., players) or other events. Simulation in a computer game uses discrete time, as the state of the environment is inspected in discrete points in time. This is called discrete event simulation. Inspection of the states does not necessarily have to be inspected at even intervals, but when something occurs that can change a state in the system. Events are placed in an event queue and ordered by the timestamp of their scheduled execution. An example can be a simulated airplane, which is scheduled to land at time t, for which an event *landing* is added to the event queue. Time t will be the next point of time when the airplane has to be inspected again. However, if something happens in the system that can affect the plane before landing, then an earlier placed event might have to be removed from the event queue. Game engines run a game loop, which dictates the minimum time step between two sequential events. Typically, game optimizations make sure that only events related to objects which need to be inspected at that time are inspected and they can be also prioritized based on the importance of the object (e.g., visible to player, affect game play fairness, and correctness). In practice that can mean that less important events are placed to an event queue further apart in time.

Game Simulation in Distributed Environment

Sharing of a game environment between multiple players with their own game devices adds another dimension. There is usually some uncertainty between the game (simulation) states in each device, which is caused by the message exchange latency. The impact of this latency increases with the demand of more frequent game state updates. For example, in an ice hockey game, each player plays the game in their own computer, which is modelling the game simulation, and controls one of the ice hockey players. The game state in each computer should not differ too much to make the play experience acceptable.

In distributed simulation, there are two approaches for managing uncertainty and ensuring correctness of the simulation: conservative (Chandy and Misra 1979) and optimistic (Jefferson 1985) approaches. In a conservative approach, each simulation agent (or game client) reports how far in time they have progressed. They can only progress within some preselected time boundaries of each other. Conservative approaches are not generally used in action games because they are limited by the speed of the slowest client (or the longest latency). In optimistic approaches, each client can simulate the game as fast as they can, but if an error is detected they have to do a rollback, i.e., they have to undo things that went wrong in the simulation, and correct game states, which can cause more rollbacks. These synchronization problems can be seen, e.g., as an opponent avatar changing position suddenly. Game interfaces try to hide these

synchronization errors, e.g., by using start movement animations, which can lead to failed action as needed.

As the network is one of the critical resources, it is important to try to limit the frequency of synchronizations and the volume of exchanged messages. Methods like dead reckoning (Pantel and Wolf 2002), in which the next position of an object is estimated from current movement, are used to reduce needed update frequency. Analysis of synchronization problems with their solutions are available for the games Halo: Reach (Aldridge 2011) and Age of Empires (Bettner and Terrano 2001).

Extensive work has been done in standardization to connect distributed simulators, especially related to serious gaming. High-level architecture (HLA) (IEEE Std 1516 2010) is an interoperability standard to integrate a number of separate simulations into one and used, for example, in military war games. An alternative standard is Distributed Interactive Simulation (DIS) (IEEE Std 1278.1 2012).

Conclusion and Discussion

Impact of the network is an aspect that should be considered from the beginning of a multiplayer game design. In many cases in the early 1990s, game developers produced games, which were later decided to include Internet multiplayer possibility. The complexity of adding the multiplayer option turned out to be more challenging than it was pre-seen and typically took considerably more time to get working than was expected. These problems have not disappeared today, and game designers have to consider how the synchronization between the game simulations is done in sufficient way to ensure good user experience and scalability.

Diversity in Gaming and the Metaverse

Stefania Bau and Rachel Power
Init Esports, Lewes, DE, USA

Synonyms

Cross-culturalism; Cultural diversity; Cyberspace; Digital sports; Electronic sports; Esports; Ethnic inclusiveness; Multiculturalism; Multiverse; Virtual reality

Definition

The metaverse is a digital reality that combines aspects of social media, online gaming, augmented reality (AR), virtual reality (VR), and cryptocurrencies to allow users to interact virtually (Folger 2021).

Gaming or Esports are competitive digital tournaments (sports) held online, in real life, and also in the metaverse.

Diversity (Diversity and Inclusion Definitions) is the range of human differences, including but not limited to race, ethnicity, gender, gender identity, sexual orientation, age, social class, physical ability or attributes, religious or ethical values system, national origin, and political beliefs (n.d.).

Introduction

This entry is a commentary on the current state of diversity in the digital world and what opportunities the future may hold in the new ecosystem (metaverse).

The human fascination with a virtual world is not a new concept. Video games have been around since 1947 (Early history 2021; Wikimedia Foundation 2021) but the first game that really launched the industry can be attributed to physicist William Higinbotham who created a simple tennis game in October 1958 that became a big hit at the Brookhaven National Laboratory open house (Tretkoff 2008; October 1958: Physicist invents first video game n.d.). In the early days, a video game was a computer-generated program intended to deliver fun to the user that was performing certain tasks. Today the scope remains the same, but the level of engagement is almost limitless. From one user interacting with a computer to today's virtual worlds, the digital gaming evolution has moved quickly into our lives with both positive and negative results.

With the rapid growth of the World Wide Web and access to information, people are becoming more educated, more connected, and more informed. Although there still exists a digital divide or gap in access for some demographics, diverse populations are more connected than ever before. People interact globally through many different platforms including social media, communication applications, and online gaming (esports). With a more integrated society, cultural differences come to the surface which allows people to learn about different traditions, values, and belief systems. These tools that connect the world can bring people together based on a common interest, and this is a powerful way to build bridges and discourage prejudice.

Ideally, everyone can play in this virtual world of esports and gaming where they can truly become what/who they want regardless of physical, economic, or other disadvantages. At the heart of esports is an inclusive ecosystem. Unfortunately, the reality turns ugly when people are not accountable for their digital actions. The interconnectivity and the possibility to hide behind a screen can fuel cyber bullying when some people exploit the anonymity of a gamer-tag (a player's chosen name while gaming) to be abusive to others without consequence. Gaming communities tend to be a tight nit group because of their shared passion. The social connection is important and can be difficult for a person that does not fit in with the group. When an ecosystem is not welcoming and safe, it does not breed diversity. Whereas on one side, esports is about entertainment and fun, there is an ugly side of the virtual world that lacks the checks and balances to prevent people from behaving badly. However, a solution may be just around the corner. There are many companies that are working on creating programs that can help solve this issue with a digital identity for every individual. The goal is to develop accountability and regulations, so the virtual world can be safe for everyone as the metaverse becomes more mainstream.

The term metaverse (Frey 2021) was first used in the 1992 novel "Snow Crash" by Neal Stephenson. In 2003, Linden Lab built an on-line platform called "Second Life" where people could create an avatar (digital persona) and have a second life in a virtual world. In 2011, author Ernest Cline gave a then-new interpretation of a virtual world in his novel (Cline 2011) "Ready Player One." Cline tells the story of how a videogame character

comes to life in the year 2045 and therefore owns its position in the virtual world. He imagined what it would be like for a player to experience a transformative participation where the player/character was not anymore just "behind the screen" but was sort of "within the screen." Visionaries had already started putting together the building blocks of this imaginary digital world and soon after mainstream companies pivoted to align with this emerging technology. New decentralized currencies have been introduced as the world started its next phase of a digital revolution. In 2020, while in the midst of a global pandemic, people across the globe were stuck at home with limited ways to socialize, so they turned to the digital world to escape reality. The concept of a metaverse became truly mainstreamed in 2021 when Facebook's parent company changed its name to Meta.

What part diversity can play in all of this? Imagine a completely new world in a digital form created by people from different backgrounds. In this world, everyone will have their own avatar that can perform actions one could have only dreamed of before. Now imagine that all of these avatars have a digital identity, so everyone can feel safe and welcome. The metaverse is an opportunity to create an ecosystem where everyone is equal. It is also a new frontier to explore proof of concept, test new research, or prototype new products to then be reproduced in real life. The opportunities are endless. With the power of connectivity, people from less privileged communities can have a chance of making a mark in a world with a lower barrier of entry. Society has a new chance to do this right and, hopefully, everyone will embrace it. Full inclusivity is now just a click away. Only time will tell.

Dōjin Game

Mikhail Fiadotau
Centre of Excellence in Media Innovation and Digital Culture, Tallinn University, Tallinn, Estonia

Synonyms

Doujin Game

Definitions

Dōjin games (alternatively romanized as doujin) are digital games made by individuals or small teams of enthusiasts, referred to as dōjin circles. Alongside other media such as manga comics, literature, anime, and music, these games are part of the wider dōjin scene, which originated in Japan and which revolves around a shared appreciation of popular culture.

Overview

Kenkyūsha's New Japanese-English Dictionary (2003) explains the term *dōjin* (同人) as being short for *dōshi-no hito* (同志の人), or "like-minded person, kindred spirit." The word *dōjin* is generally used to refer to small groups (*sākuru, "circles"*) of individuals brought together by their shared tastes in popular culture, who produce self-published works such as literature, manga comics, digital games, literature, and/or music. Although most dōjin producers are hobbyists, some are professional or semi-professional artists, writers, game designers, etc. (Hichibe and Tanaka 2016). Fan works (*nijisōsaku*) based on worlds and characters from popular culture make up much of dōjin scene; yet original works are also common (Lamerichs 2016). A significant proportion of dōjin works are erotic or pornographic in nature (Watabe 2013), with many fan works seeking to extend the fictional worlds of popular culture into the realm of erotic fantasy.

By contrast to Japan's mainstream gaming, which revolves largely around game consoles and to a lesser extent amusement arcades, dōjin games, also referred to as *dōjin sofuto*, are primarily designed for the personal computer (Hichibe and Tanaka 2016). Most of these games belong to one of a handful of typical genres such as visual novels, role-playing games, and scrolling shooters. Thematically and aesthetically, they usually cater to established niches such as *bishōjo* (male-oriented games featuring beautiful girls), *otome* (games for young women focusing on relationship building, usually with a handsome male character), *yaoi* (games depicting homoerotic relationships between male characters, but generally intended for female consumption), and so on.

While there are many dōjin shops in Japan, specializing in dōjin manga (dōjinshi), games, and music, dōjin works can also be found in mainstream manga and game shops. However, the most visible venue for dōjin work dissemination is the semi-annual Comic Market convention in Tokyo (Lam 2010). Smaller local events and conventions also play an important role.

Despite originating from Japan, dōjin culture has extended to other countries in the region such as China (Si 2015), Taiwan (Chiang and Lo 2012) and South Korea (Yoon 2015). Moreover, it has had considerable cultural impact in the West as well, leading creators to appropriate some of its genres and conventions (Lamerichs 2016).

History

While dōjin games are a relatively recent addition to the wider dōjin culture, the culture itself has its origins in the late nineteenth–early twentieth century dōjin literary circles (Morishita 1980). These circles produced self-published literary magazines such as *Bungakukai* and *Shinshichō*, which were

highly influential in Japan's pre-war literary scene (Encyclopedia Nipponica 1994). In the post-war period, some of these magazines began to include manga; dedicated dōjinshi manga magazines, such as Shōtarō Ishinomori's *Bokujū Itteki*, were also increasingly published (Kálovics 2016). Self-published manga gradually became a fixture at science fiction conventions, and in 1972, *Nihon Manga Taikai*, a dedicated manga convention, was held for the first time, with some booths selling dōjinshi magazines (Iizuka 2017).

However, the biggest impetus to the development of dōjin culture was the emergence of the Comic Market (or Comiket) in 1975 (Lam 2010). Whereas the first grassroots convention attracted 32 dōjin circles and about 700 attendees, today Comiket brings together around 500,000 participants on average who buy and sell dōjin manga, novels, and games, as well as engage in cosplay and other activities.

The appearance of home computers such as MSX and NEC PC-88 in the 1980s enabled hobbyist developers to create their own computer games, which began to find their way into dōjin culture. Visual novel *Ningyo no Namida* ("The Mermaid's Tears"), released in 1984 by Teikoku Soft, is considered to be the first dōjin game to be exhibited at a Comiket. By the end of 1980s, computer games had become a staple at dōjin conventions. In 1988, *Pasoket*, a spinoff of Comiket focusing on games, began to take place in cities across Japan on a monthly basis (Hichibe 2013).

More recently, the advent of digital distribution has further widened the reach of dōjin games, many of which are now sold (or distributed for free) online, with an increasing number found on global distribution platforms such as Steam and Apple's App Store (Hichibe and Tanaka 2016).

Specificity and Significance

Dōjin games are often compared to the Western phenomenon of indie games (Picard 2013; Consalvo 2016), but there are important differences between the two. While indie games stress the artistic independence of their creators and distance themselves from mainstream gaming (Garda and Grabarczyk 2016), many dōjin games are in fact fan works based on mainstream games. Additionally, dōjin games are one part of a close-knit transmedia continuum also including manga, anime, literature, music, etc.

The lack of opposition towards mainstream gaming and the close integration with other media means that some dōjin games achieve wide recognition beyond both the niche of dōjin culture and the cultural form of game. One example is *Higurashi no Naku Koro ni* ("Higurashi: When They Cry"), which started in 2002 as a horror visual novel sold at the Comic Market but has now evolved into a transmedia franchise comprising an anime series, a manga, a live action film, multiple novels, and an action game (Wheeler 2011), reflecting how interconnected Japan's "media mix" (Steinberg 2012) is.

The integration of dōjin content with mainstream media and major distribution networks is also interesting from another perspective: that of copyright. The co-existence of mainstream works and fan-made "parodies" (often of an erotic nature) on manga and game shop shelves can hardly be explained through the Western copyright framework. Such a status quo, albeit precarious from a legal standpoint (Noppe 2010), offers a vision of how copyright holders can interact with fan producers – and how creativity can emerge at the intersection of independent production and fandom.

Domain-Specific Choices Affecting Design Effort in Gamification

Amol D. Mali[1] and Kompalli Jwala Seethal Chandra[2]
[1]Computer Science Department, University of Wisconsin-Milwaukee, Milwaukee, WI, USA
[2]Microsoft Corporation, Redmond, WA, USA

Synonyms

Choices in games; Edutainment; Game design; Game production effort; Gamification

Definitions

Gamification: It is the process of modifying an activity which does not include elements of a game, to allow the performer of the modified activity to (i) improve knowledge or skill using the feedback from the mechanism built into the modified activity while being entertained through text, pictures, animations, video, or audio, (ii) dynamically earn rewards, (iii) win, or (iv) be dynamically ranked, by fulfilling relevant conditions, such that the overall experience of the performer of the modified activity is different from the experience of getting points, grades, certificates, gifts, payments, or prizes based on paid/volunteer work, shopping, or assessment similar to that in schools or colleges.

Introduction

Santos and others (Santos et al. 2018) report on how requirements analysis, test planning, test design, test execution, and test closure for computer games differ from these activities for software which is not a game. Though there is lot of theoretical and empirical work on estimating the effort needed for development, testing, and maintenance of software, estimation of effort for designing, developing, and testing computer

games remains underexplored. Identifying domain-specific choices affecting game-design effort has several uses. Design influences the effort for development, testing, and documentation. This affects budget of the project, quality of the game, and the temporal schedule of game production. Indicators of game-deign effort can be used in predicting if the game can be produced while meeting budgetary, temporal, and quality-related requirements. This helps in adjusting scope of the game. Since design of computer games is usually open-ended because of game design being highly creativity-based, theory of computer games continues to evolve. Identifying domain-specific choices in design of computer games is also useful for refining the theory of computer games that captures breadth, depth, and diversity in this field. This article identifies many of the key domain-specific design choices in games for motivating people, teaching people to recognize objects, and teaching a language, engineering design, computer programming, or algorithm development, and shows how identifying domain-specific choices in game design can be useful.

Gamification for Motivating

Bianchini and others (Bianchini et al. 2016) present a web-based mobile platform for e-participation of administrators and citizens. This platform allows citizens and administrators to submit and share problems, initiatives, and solutions. Other citizens within the same municipality can add their own solutions. Citizens obtain points for submitting proposals and solutions. A citizen gets an extra point for each detail added to the solution and each vote received on the solution. Administrators can award additional points. *Leaderboard of New Solutions*, *Leaderboard of Completed Solutions*, *Leaderboard of Citizens*, and *Leaderboard of Proposals* are used to assign black, silver, and gold medals to citizens. An administrator can assign a blue medal. Medals enable citizens to change their level. Level 1 has interested citizens. Level 2 has active citizens. Level 3 has distinguished citizens. The governance of the municipality may publicly reward the winner of *Leaderboard of Distinguished Citizens* each year.

Butler and Ahmed (2016) present a game to motivate students to achieve computer-science-learning goals. The first level of the game introduces stacks and queues. The second level of the game includes Selection Sort, which is a sorting algorithm. A player is a cadet at a space academy and has his/her own robot to control and customize while performing missions.

A list of key design choices in gamifying the process of motivating people to achieve a goal is provided next.

(i) Goals for which to motivate the player, e.g., blood donation, monetary donation, studying for an international competitive examination, volunteering at a retirement home, and volunteering at a public library
(ii) Number and types of activities that directly motivate the player to achieve the relevant goal by issuing rewards that the player can show others if he/she wishes (e.g., an email sent to friends or relatives of the player when the player donates the correct quantity of blood at a location where it is most needed is a reward that directly motivates the player to donate blood in virtual world, and it is hoped that the player will be motivated to donate blood in the real world after playing this game)
(iii) Number and types of activities that indirectly motivate the player to achieve the goal, e.g., taking a tour of a hospital in digital world showing suffering of patients in need of blood
(iv) Number and types of activities to include to teach undesirable consequences of overdoing the activities that the game motivates the player to perform

Gamifying Object Recognition

Teaching players to recognize objects has numerous advantages, e.g., players can use the ability to

recognize objects in a domain in shopping, repairing machines, supplying parts, and reporting diagnosis of dysfunctional machines. A list of key design choices in gamification of object recognition is provided next.

(i) Types of objects to include in the game, e.g., plants and animals
(ii) Objects of chosen types to include in the game, e.g., cabbage, spinach, and carrots
(iii) Shapes, designs, colors, sizes, and orientations of objects, e.g., red cabbage and green cabbage
(iv) Lighting conditions in the region containing the object/objects to be recognized
(v) Whether to simultaneously show multiple objects for the player to recognize or not
(vi) Whether to show a part of the object to be recognized instead of the entire object
(vii) Whether to allow objects to touch each other or partially block the view of other objects or not, if multiple objects are to be shown simultaneously
(viii) Whether to show damaged objects or not
(ix) Types of damage to show
(x) Whether to include objects that are not damaged but have an undesirable appearance or not, e.g., cups with dust that can be removed by washing
(xi) Whether to include irrelevant objects or not
(xii) Maximum number of objects to show simultaneously
(xiii) Number of images of an object to show
(xiv) Whether to show multiple images of an object simultaneously or sequentially
(xv) Whether to show three-dimensional version of an object or its 2D projections, e.g., view from top, view from bottom, view from front side, and view from rear side
(xvi) Types of clues and number of additional clues to give to help in recognizing the object, e.g., sound made when the object falls on wood or concrete, changes in the object with variation in temperature, and changes in the object due to chemical reactions

Gamifying Language Learning

A gamification of Mandarin learning is presented in (Heryadi and Muliamin 2016). They divided the learning material among the following categories: (i) Greetings, (ii) Family, (iii) General conversation, (iv) Colors, (v) Numbers, (vi) Days and months, (vii) General vocabulary, (viii) Food, and (ix) Animals.

A list of key design choices in gamification of language learning is provided next.

(i) Languages to teach
(ii) Native languages to include in the game
(iii) Number of letters or symbols of the alphabet to show at a time
(iv) Number of words to show at a time
(v) Number of sentences to show at a time
(vi) Number of words in a sentence
(vii) Order in which to show letters, symbols, words, or sentences
(viii) Whether to show incomplete words or sentences or not
(ix) Number of letters to exclude from words and number of words to exclude from sentences, when the player is expected to enter missing letters or words
(x) Number of writing styles to use to generate letters, symbols, words, and sentences
(xi) Number and types of accents in the audio clips containing pronunciations of letters, symbols, and words
(xii) Minimum number of letters in words, minimum number of words, minimum number of sentences, minimum number of words in individual sentences, or the lower limit on the total number of words the player is expected to type or speak, if the player is asked to type or speak as much as possible in the given time
(xiii) Number of irrelevant symbols, letters, words, pictures, or sentences to include for the player to identify the relevant ones
(xiv) Types of pictures and number of pictures to include if the player is expected to match them with text, type relevant text, or speak in response to the shown picture/pictures

(xv) Number and types of pictures to include if the player is expected to order them based on the words in the given sentence or based on the given sentences
(xvi) Number and types of words whose meanings to include to create a verbose text that the player is expected to make concise by replacing the meanings with corresponding words
(xvii) Number of words, sentences, and clusters, and clustering criteria, when the player is expected to group words or sentences based on the given criteria, e.g., putting synonyms together, putting words or sentences related to airports together, etc.
(xviii) Number of clusters and number of words or sentences in individual clusters, when the player is expected to identify the criteria used to create the clusters
(xix) Number and types of words, sentences, or paragraphs to include in the text that the player is expected to summarize
(xx) Minimum and maximum number of characters, words, or sentences in the player's answers to free-response questions
(xxi) Themes for free-response questions

Gamifying Engineering Design

A list of key design choices in gamification of engineering design is provided next.

(i) Whether to expect the player to design an entire product or a part of it
(ii) Products and parts to design fully or partially
(iii) Number of design steps to show to the player at a time, if the player is taught by having him/her reorder the given steps
(iv) Number of irrelevant steps to show to the player at a time, if the player is taught by having him/her remove irrelevant steps from the given steps
(v) Number and types of mistakes to introduce within individual steps, if the player is expected to correct mistakes in individual steps, e.g., incorrect choice of materials, incorrect assumptions, incorrect units, and incorrect variables, constants, and mathematical operators in equations
(vi) Number and types of steps to exclude, if the player is expected to detect that some steps are missing, and is expected to provide them
(vii) Amount and types of information to exclude from individual steps if the player is expected to detect incompleteness within individual steps and make the steps complete by providing the missing information
(viii) Number and types of choices to provide to the player at a time when the player is taught to design by having him/her make choices incrementally
(ix) Number and types of designs or design steps to include to have the player rate, classify, or order them
(x) Number and types of design questions and number and types of answers to include when the player is expected to match questions with answers
(xi) Whether to limit the game to teaching to produce feasible designs or include optimal designs too
(xii) Factors to include besides safety and durability, e.g., manufacturability, sustainability, and cost
(xiii) Number and types of differences to introduce between two designs or steps, when the player is expected to compare them and find as many differences as possible
(xiv) Number and types of facts about designs to include if short questions are to be posed to the player
(xv) Number of products or parts to include in the set of options when the player has to choose the products or parts the given design steps are relevant to, from the given options
(xvi) Number and types of opportunities to include in a correct design for the player to detect and improve the design
(xvii) Number and types of steps in the design of different products or different parts to present to the player as if all of these steps are

for designing only one product or only one part, for the player to associate the steps with different parts or products

(xviii) Number and types of designs or design steps to present to the player when the player is expected to identify why they are ordered, rated, or clustered the way they are in the challenge

Gamifying Algorithm Development

A list of key design choices in gamification of algorithm development is provided next.

(i) Types and number of algorithms to include in the game

(ii) Whether to design challenges based on an entire algorithm or a part of it

(iii) Whether to expect the player to design an entire algorithm or a part of it

(iv) Whether to expect the player to analyze an entire algorithm or a part of it

(v) Type of analysis to include in a challenge (e.g., completeness, optimality, time complexity, and space complexity)

(vi) Number and types of steps of an algorithm to show to the player at a time, for analyzing them

(vii) Number and types of subtasks within an algorithm to present to the player for him/her to provide a part/parts of the algorithm

(viii) Number of steps of an algorithm to show to the player at a time, if the player is taught by having him/her reorder the given steps

(ix) Number of irrelevant steps to show to the player at a time, if the player is taught by having him/her remove irrelevant steps from the given steps

(x) Number and types of mistakes to introduce within individual steps, if the player is expected to correct mistakes in individual steps, e.g., incorrect choice of data structures, syntactic errors, incorrect mathematical operators, variables, or constants, and incorrect type of statement

(xi) Number and types of steps to exclude, if the player is expected to detect that some steps are missing, and is expected to provide them

(xii) Amount and types of information to exclude from individual steps if the player is expected to detect incompleteness within individual steps and make the steps complete by providing the missing information

(xiii) Number and types of choices to provide to the player at a time when the player is taught to design an algorithm by having him/her make choices incrementally

(xiv) Number and types of algorithms or steps in algorithms or steps in algorithm analysis to include, and have the player rate, classify, or order them

(xv) Number and types of design or analysis questions and number and types of answers to include, when the player is expected to match questions with answers

(xvi) Whether to limit the game to teaching to design sound algorithms or include algorithm optimization too

(xvii) Factors to include besides soundness, e.g., ease of modification to handle extra inputs or inputs of different types, ease of modification to produce a solution meeting additional or different requirements, and ease of modification to find more than one solution or count the number of possible solutions

(xviii) Number and types of differences to introduce between two designs or steps, when the player is expected to compare them and find as many differences as possible

(xix) Number and types of facts about algorithms to include if short questions are to be posed to the player

(xx) Number of problems to include in the set of options when the player has to choose the problems the given algorithm steps are relevant to

(xxi) Number and types of opportunities to include in a correct algorithm or analysis of an algorithm, for the player to detect and improve

(xxii) Number and types of steps from different algorithms or their analyses to present to the player as if they are steps for only one algorithm or its analysis, for the player to associate the steps with corresponding algorithms or analyses
(xxiii) Whether to include parallel algorithms or not
(xxiv) Number and types of steps or algorithms to present to the player to parallelize
(xxv) Number of parallelizable steps to include along with inherently-sequential steps, when the player is expected to classify each step as parallelizable or inherently sequential
(xxvi) Number and types of algorithms or their parts to present to the player when the player is expected to identify why they are ordered, rated, or clustered the way they are in the challenge

Gamifying Programming

Carreno-Leon and others (Carreno-Leon et al. 2018) present the use of gamification in a course on introduction to programming. In the first level, the student is given only those cards that appear in solution. In the second level, the student is given more cards with pseudocode fragments than needed, but the number of cards needed in solution is disclosed. In the third level, the student is given more cards than needed and not told how many are needed in solution.

A list of key design choices in gamification of programming is provided next.

(i) Programming paradigms
(ii) Programming language/languages
(iii) Features of programming language/languages to cover in the game
(iv) Number and types of programming tasks
(v) Whether to design a challenge based on an entire program or a part of it
(vi) Whether to expect the player to provide an entire program or a part of it
(vii) Whether to expect the player to analyze an entire program or a part of it
(viii) Types of program analysis to include in a challenge (e.g., guarantee of finding a solution, optimality, dealing with invalid inputs, comments for understanding and modification, running time, and memory needed)
(ix) Number and types of steps of a program to show to the player at a time, for analyzing them
(x) Number and types of subtasks fulfilled by a program to present to the player for him/her to provide the corresponding part/parts of the program
(xi) Number of steps of a program to show to the player at a time, if the player is taught by having him/her reorder the given steps
(xii) Number of irrelevant steps to show to the player at a time, if the player is taught by having him/her remove irrelevant steps from the given steps
(xiii) Number and types of mistakes to introduce within individual steps, if the player is expected to correct mistakes in individual steps, e.g., incorrect choice of data structures, syntactic errors, incorrect mathematical operators, variables, or constants, and incorrect type of statement
(xiv) Number and types of steps to exclude, if the player is expected to detect that some steps are missing, and is expected to provide them
(xv) Amount and types of information to exclude from individual steps if the player is expected to detect incompleteness within individual steps and make the steps complete by providing the missing information
(xvi) Number and types of choices to provide to the player at a time when the player is taught to write a program by having him/her make choices incrementally
(xvii) Number and types of programs or steps from programs or steps from program analysis to include, to have the player rate, classify, or order them
(xviii) Number and types of design, implementation, or analysis questions, and number

and types of answers to include, when the player is expected to match questions with answers

(xix) Whether to limit the game to teaching to write correct programs or include program optimization too

(xx) Factors to include besides correctness, e.g., ease of modification to handle extra inputs or inputs of different types, ease of modification to produce a solution meeting additional or different requirements, ease of modification to find more than one solution or count the number of possible solutions, ease of modification to handle other data structures, and ease of rewriting in a different programming language

(xxi) Number and types of differences to introduce between two programs or steps from programs, when the player is expected to compare the two and find as many differences as possible

(xxii) Number and types of facts about programming to include if short questions are to be posed to the player

(xxiii) Number of problems to include in the set of options when the player has to choose the problems the given program steps are relevant to

(xxiv) Number and types of opportunities to include in a correct program or correct analysis of a correct program, for the player to detect and improve

(xxv) Number and types of steps from different programs or their analyses to present to the player as if they are steps from one program or its analysis, for the player to associate the steps with corresponding programs

(xxvi) Whether to include parallel programs or not

(xxvii) Number and types of steps or programs to present to the player to parallelize

(xxviii) Number of parallelizable steps to include along with inherently-sequential steps, when the player is expected to classify each step as parallelizable or inherently sequential

(xxix) Number and types of programs or their parts to present to the player, when the player is expected to identify why they are ordered, rated, or clustered the way they are in the challenge

Usefulness of Identifying Domain-Specific Choices

Domain-specific choices like the ones we identified for six domains, directly or indirectly affect the effort needed to design characters, actions, feedback, rules, challenges, hints, rewards, punishments, gaming world, challenge-adaptation mechanisms for keeping the player motivated and interested, surprises, levels, fairness-enforcement mechanisms, cheating-detection mechanisms, elements relevant to players with special needs, and a multiplayer version. They also directly or indirectly affect the effort needed for localization. Identifying domain-specific choices is useful in several ways. These choices allow us to use counting techniques from discrete mathematics to quantify some components of the gaming experience. Identifying these choices allows us to compare them to know which choices have a bigger impact on the effort needed for game design, development, and testing. This helps in deciding which choices to use. Identifying domain-specific choices can be useful in speeding up game design, development, and testing, by reusing design, code, and test plans of a game from domain D' to create a game in domain D'' when D'' and D' have similar domain-specific choices.

Dynamic Music Generation: Audio Analysis-Synthesis Methods

Gilberto Bernardes and Diogo Cocharro
INESC TEC and University of Porto, Faculty of Engineering, Porto, Portugal

Synonyms

Adaptive music systems; Audio collage; Audio mosaicing; Concatenative sound synthesis; Interactive music systems

Definitions

Dynamic music generation systems create ever-different and changing musical structures based on formalized computational methods. Under scope is a subset of these methods which adopt musical audio as a strategy to formalize musical structure which then guides higher-level transformations to be synthesized as new musical audio streams.

Introduction

Technologies which adhere to nonlinear, as opposed to fixed, storytelling are becoming pervasive in the digital media landscape (Lister et al. 2003). In this context, methods for dynamically generating music have been prominently and

increasingly adopted in games, virtual and augmented reality, interactive installations, and 360 video. Their adoption is motivated by a wide range of factors from computational constraints (e.g., limited memory) to enhanced interaction with external actuators and artistic endeavor.

Dynamic music generation systems are typically driven by formalized or algorithmic methods whose history is interleaved with modern computing (Nierhaus 2009). This article reviews a subset of these systems which adopt musical audio as a source to formalize musical structure algorithmically, which is then used to guide the generation of new musical streams by synthesizing sub-audio clips from the musical audio source – an approach addressed as musical audio analysis-synthesis.

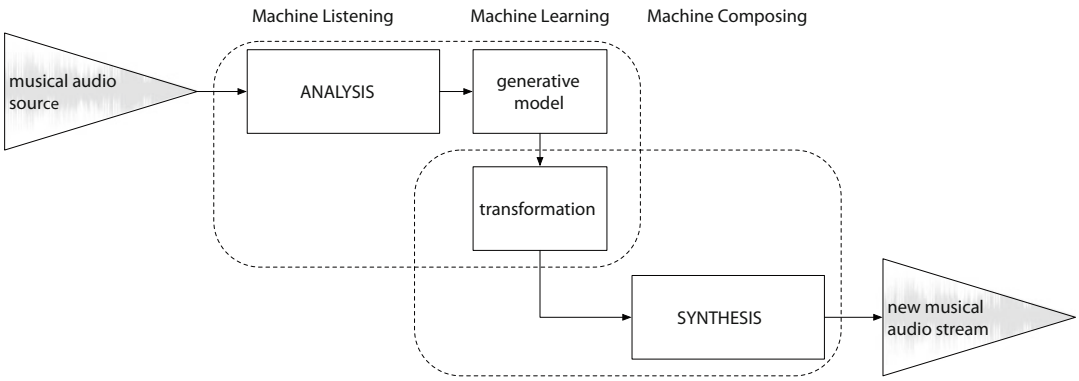
The remainder of this entry details a typical architecture of a generative musical audio analysis-synthesis system (section "From Sound to Musical Audio Analysis-Synthesis Systems") and presents an overview of its applications scenarios (section "Applications").

From Sound to Musical Audio Analysis-Synthesis Systems

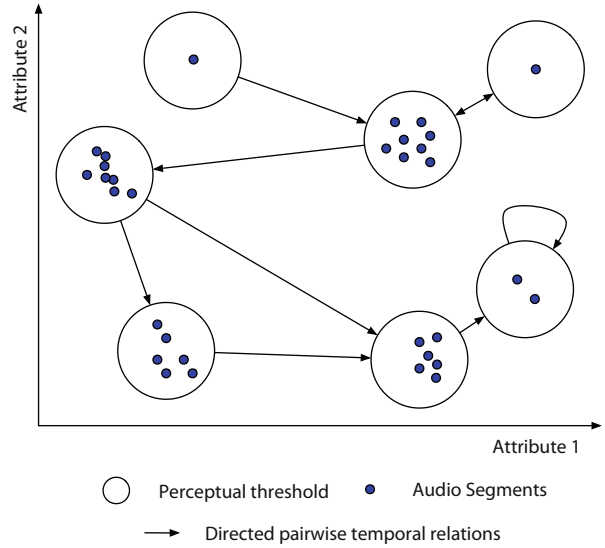
Audio analysis-synthesis methods break down a sound into some essential, measurable attributes (e.g., amplitude or pitch) to guide *sound* transformations during (re-)synthesis (Jehan 2005). Historically, these transformations exist at the sample level and follow an adaptive audio effect architecture (e.g., compression) (Verfaille and Arfib 2001). Recent advances in the hierarchical analysis and generation of musical audio structure have expanded the transformations beyond the sample level towards *music* processing (e.g., automatic remixing).

Analysis-synthesis systems for dynamic generation of musical audio mimic fundamental perceptual and cognitive human functions in a threefold component architecture of machine listening, learning, and composing (see Fig. 1). Machine listening and learning are two intertwined components which primarily adopt bottom-up (or content-driven) processing methods to infer hierarchical structure from audio samples. It comprises two main tasks: multilevel (beat, downbeat, phrase, and section) segmentation and the description of its temporal structure. Inferred information tends to be represented as graphs, whose nodes represent segmented musical structures, and directed pairwise links their temporal relations (see Fig. 2). The resulting representation provides a robust means for computational structure discovery, notably by finding redundant information across the temporal structure which can be clustered according to some (perceptually guided) similarity metric (see Fig. 2).

Typically, each node or segmented musical audio structure is represented in the system by a *feature vector*, i.e., a set of numerical features that result from measurable musical attributes, such as pitch, loudness, and percussiveness. The choice of such attributes, the metrics used to compare them,



Dynamic Music Generation: Audio Analysis-Synthesis Methods, Fig. 1 Architecture of a musical audio analysis-synthesis system for dynamic generation



Dynamic Music Generation: Audio Analysis-Synthesis Methods, Fig. 2 Illustration of a graph model of musical audio structure. The space is defined by (perceptual) attributes (reduced in this illustration to two dimensions). Musical audio segments are understood as data points, represented as circles, whose locations are defined by their attributes in the descriptor space. Small segment distances denote higher (perceptual) similarity in the descriptor space. The circumferences define a perceptual threshold used to cluster similar-sounding segments

and the perceptual threshold used to define the maximum degree of dissimilarity among segments are crucial to the graph design. All these variables are commonly set manually by the users due to their subjective nature and implications in the resulting musical output of the system (i.e., synthesis). To a certain extent, the choice of such variables is akin to the role of sketches and raw material in the compositional process. For a comprehensive comparison of these variables and their implications in the musical results, please refer to Norowi et al. (2017).

If the resulting structural model has sufficient redundancy, machine composing can then traverse the directed links of the graph to create ever-different and changing musical streams which retain the (higher-level) structure of the audio source captured by the model. The output of an analysis-synthesis systems is *musical collages* made of rearranged segments or audio snippets from the original or source audio. The structure of the output musical audio can be understood as a variation of particular features temporal evolution of the source, thus retaining some level of similarity while allowing its indeterminate temporal expansion.

Applications

We present a user-centered perspective of applications for dynamic generation of musical audio through analysis-synthesis approaches. Our twofold fuzzy categorization is rooted in the nature of processed signals and distinguishes (natural or synthetic) sound textures and soundscapes from music. A distinction is made concerning the structure of the audio signal content (e.g., noisy vs. pitched or nonmetric vs. metric) rather than any discrimination based on artistic merit, since both categories (music and soundscapes) can be understood as the product of creative-oriented practices.

The generation of sound textures and soundscapes using analysis-synthesis methods has been applied in audio postproduction for television and film as well as in sound design for games and interactive installations. It mostly tackles the pervasive problem of extending a given audio clip in postproduction whenever the prerecorded audio does not cover the entire duration of a scene (Frojd and Horner 2007; Bernardes et al. 2016). Moreover, some analysis-synthesis soundscape systems also enable to procedurally generate highly controlled nuances that match

external actuators (Bernardes et al. 2013; Schwarz and Schnell 2010). For example, in a game engine, the player behavior can be mapped to soundscape parameters, such as density of events and spectral richness, to enhance the playability through symbiotic relations across modalities.

The generation of music using analysis-synthesis methods has been mainly applied as (online) performance or (offline) computer-assisted composition tools. In the first scenario, it has been highly explored in interactive music systems for human-machine improvisation, where co-improvising machines aim to capture and emulate the musician's style (Schwarz et al. 2006; Assayag et al. 2006; Surges and Dubnov 2013; Pachet et al. 2013; Einbond et al. 2016). The second scenario has been highly explored to guide the search for variations of a given musical audio excerpt in the realm of entertainment technologies or composition of a given user-defined musical audio (Jehan 2005; Bernardes et al. 2013; Lamere 2012; Davies et al. 2014).

Educational Game Abzû and the Lens of Fun Learning

Kyle McCarter[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Abzû; Educational games; Fun learning

Definition

Educational games – Games that are explicitly designed with educational purposes by helping players learn a concept, a historical event, or a skill as they play.

Lens of fun learning – A critical thought process by applying the concept of fun learning in scrutinizing or analyzing a game.

Learning should be fun. How does an educational game like Abzû hold up when scrutinized by the lens of fun learning? Released in 2016, Abzû is an adventure video game developed by Giant Squid Studios and published by 505 Games for PlayStation 4, Xbox One, Nintendo Switch, and Microsoft Windows. Abzû is named after the freshwater god in the Ancient Mesopotamian religion (Butterworth 2016; Gaston 2016; McElroy 2016; Nava 2016).

© Springer Nature Switzerland AG 2024
N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

Abzû is similar to Journey – a 2012 indie video game developed by thatgamecompany and published by Sony Computer Entertainment for PlayStation 3 that year. Like Journey, the player starts the game waking up in a strange place without any memory. So the player starts exploring to find something that will help tell them who they are and why they are there. The major difference between Abzû and Journey is the environment. In Journey, the player is on a planet with a barren desert, whereas in Abzu the planet is completely covered in water.

In the beginning the player sees a giant area of water, and there is almost no land in sight except for a few islands here and there. The camera then begins to zoom in on what appears to be a scuba diver floating with his/her face in the water. At maximum zoom, the scuba diver wakes up, looks around, and then decides to dive under to explore. While traveling the diver meets many different types of fish, even ones that are said to be extinct. The types of fish are based on tens of thousands of real-life marine creatures. Their movements are modeled after the behavior of real fish. Artificial intelligence is used to create real-time interaction among marine animals, the diver, and the environment.

The player soon begins to notice that there are not many fish and to wonder where they could be. When the player encounters a coral reef-type object and interacts with it, the object begins to summon some fish back into the sea. As the player continues the adventure and interacts with different objects in a given area, it brings it back to life by restoring all the fish in that area of the game. The reason the fish were gone was because they were killed off by a giant evil robotic otherworldly being. Once the robot is destroyed at the end of the game, the entire ocean and its marine life is fully restored to peace and harmony.

Through the lens of fun learning, we ask ourselves what parts of a game are fun and conducive to learning and what parts need to be more fun and more conducive to learning. In Abzû, a player learns about the sea and marine life at the minimum. The game makes it fun to explore. The player can swim around in current streams with all the fish, look through caves, and explore the unknown sea where they woke up in. The game also teaches about environmental protection. When there is no pollution, the player can search under deep sea. However, when the water is polluted, the player could only see the shallow areas. Toxic water also kills all the fish that live in the affected areas.

The graphics in the game is quite pleasing in spite of limited budget on animation from a game development company. Nevertheless, it would be more fun if there are more ways to interact with the fish in addition to sonar chimes and being able to grab onto large marine animals and ride them for a short distance. All in all, Abzû is a good and elegant exemplification of a well-designed game when scrutinized with the lens of fun learning.

Definition

This article examines the design methodology of the educational VR game *Cinevoyage*, which was designed by the authors, both experienced as instructors and creators in film and animation and educational game design industries. *Cinevoyage* is designed as an educational tool for filmmaking and animation students with the aim of enhancing their knowledge and skills on *cinematic storytelling*. In this article the term cinematic storytelling refers to telling a story with moving images with respect to disciplines like scriptwriting, film grammar, cinematography, and editing. Thus, any kind of film and digital video making and drawn or computer-generated animations can be considered as a product of cinematic storytelling, if the created content is aimed at telling a story in any way, which can create emotional responses in the audience. Educational institutions teaching cinematic storytelling in any form attempt to build a curriculum that teaches certain fundamental concepts to their students. However, like in any art style, there have always been revolutionary artists who broke the existing rules and created new concepts and methodologies in certain artistic disciplines. It is mostly observed that those were the ones who knew the existing concepts and former works very well and therefore were successful in creating new ones. The educational VR game *Cinevoyage* is designed to be a supporting tool for those educational institutions which aim to transfer the general knowledge and skills on cinematic storytelling to their students, who might become the creative artists of the future.

The term *Digital Educational Game (DEG)* refers to any kind of digital game that is designed with the purpose of educating the player in a specific context (Connolly 2012). The design methodologies, the platforms they are built for, or their genres can differentiate from one DEG to another significantly. Another term *serious games* is also used commonly as an alternative to digital educational games. But serious games imply mostly business-related simulations with gamified elements (George 2017). Therefore, DEG is the preferred term within this article to describe the educational VR game *Cinevoyage* and other games that inspired its design process.

Game-Based Learning (GBL) refers to any kind of learning activity that is supported with game mechanics (Connolly et al. 2008). These games or gamified learning experiences do not necessarily have to be in digital formats (Prensky 2001). In recent years, GBL refers to the usage of both DEGs and analog games for educational purposes. These games can differ from each other in great aspects. *Cinevoyage* is an attempt to introduce GBL approach to educational institutions that aim to teach cinematic storytelling.

Virtual Reality (VR) refers to the technology and the audio-visual products that present an alternative simulated reality to the user. The technology of VR is rapidly changing but within this research, VR refers to a sensory deception within audio-visual field by using specifically built headsets. The degree of immersiveness and suspense of disbelief in VR experiences might differ in great aspects depending on many factors. Some of these factors are the processing power of the supporting computer systems, the field of view of the headsets, or the audio-visual design of the virtual world.

Introduction

As educational technologies become more accessible to the masses, more scholars and designers from various disciplines are motivated to design efficient DEGs in learning environments (Garris et al. 2002). However, it is important to keep in mind that media created for educational purposes does not guarantee a better learning outcome than the traditional teaching approaches. The famous debate between the scholars Clark and Kozma hints that it is the duty of every responsible instructional designer to ask the question whether the same educational objective can be reached efficiently without the use of expensive educational media (Clark 1994, pp. 22–23). Wouters et al. (2009) suggested that the learning outcomes, which can be attained with educational games can be classified in four different ways. These are cognitive learning outcomes (divided into knowledge and cognitive skills), motor skills, affective learning outcomes and communicative learning outcomes. As demonstrated in Bonde et al. (2014), a virtual reality educational game can increase the motivation and can be effective in achieving these learning outcomes if the media usage is combined with traditional lectures with instructors (p. 696).

This article gives an overview of the research, design, and ongoing development processes of an educational VR game *Cinevoyage*, which is the result of a master's thesis study from game design department. The objective of the game is to increase the knowledge of the students on film grammar, frame composition, storyboard creation, mise-en-scène and to improve their skills on working with professional cameras and lighting equipment under real life-like shooting conditions. For this purpose, this article reviews the design methodologies and opinions of researchers, filmmakers, and game designers on how to transfer cinematic storytelling knowledge to students in a more effective and fun way through a DEG.

Research Question

What would be the most efficient game design solution for an educational VR game, with the purpose of increasing the knowledge of the students on film history, visual language, mise-en-scène and improving their skills on working with professional cameras, lighting equipment, and other crew and cast members under real life-like shooting conditions?

Overview

The design methodology of the educational VR game *Cinevoyage* is constructed from six different DEG design methodologies. These studies are: "The FIDGE Model" (Akilli and Cagiltay 2005); "Narrative GBL objects for story-based DEGs" (Göbel et al. 2009); "Tools and methods for efficiently designing serious game" (Marfisi-Schottman et al. 2010); "A New Methodology of Design and Development of Serious Games" (Barbosa et al. 2014); "Design methodology for educational games based on interactive screenplays" (Prieto et al. 2015); "Development of design heuristics for DEGs for school children of 7 to 11 Years Old" (Khanana 2016). A summary of each methodology and how they were used during the design process of *Cinevoyage* is presented in the methodologies section.

Overall design of *Cinevoyage* is explained briefly in the research design section, where examples of DEGs, educational VR games, applications with positive learning outcomes, and inspirational cinematic storytelling works were also mentioned. During the research process, the opinions of scholars and students were asked via an online survey. Their suggestions for designing an educational VR game for cinematic storytelling were also evaluated in the findings section.

Significance of the Study

Although there are some existing or underdevelopment applications for PC, mobile, and VR platforms like Cinedesigner, Tvori, Mindshow, Source Filmmaker, Film Engine, Vpet, Tiltbrush, Oculus Medium, Limitless VR, Modal VR, Animator by Daydream, all of which might be helpful in teaching different aspects of cinematic

Educational Virtual Reality Game Design for Film and Animation, Fig. 1 Labster: equipment price comparison (EdTech Europe 2014 Innovation Showcase: Labster)

storytelling, *Cinevoyage* is probably the first educational VR game design proposal that is purely designed for educational purposes that covers many topics from curriculums of film and animation schools. Thus, there is a need for further research and development to increase the effectiveness of educational games for film and animation.

Cinevoyage combines useful mechanics and design elements from effective examples by introducing the student to a fun and engaging learning environment, which is supported with a narrative storyline, where the student can interact with famous filmmakers from film history. The game design allows the student to learn from filmmakers like Méliès, Welles, Kubrick, Hitchcock, Kurosawa, Fellini, Trier, Cuaron, etc., by visiting them in the virtual filmmaking environments based on the real sets from their works. This might allow the student to experience a simulated face-to-face lecture by one of her/his role models from the history of filmmaking. Thanks to this interaction, the increasing emotional response by the student can boost motivation and strengthen the effectiveness of learning.

One of the main reasons that Cinevoyage is designed as a VR educational game is that it may provide a virtual simulated practice environment for film and animation students. The students can increase their theoretical knowledge and practical skills on certain equipment like professional film cameras, different types of lighting, and additional supportive grip equipment like dollies, cranes, and many more. Like in the example of the gamified educational VR application Labster (Fig. 1), which provides a practicing area in a virtual science lab with simulated versions of very expensive equipment, *Cinevoyage* is also designed with a similar purpose for film and animation schools. With implementing *Cinevoyage* in their curriculum, the educational institutes can reduce the cost of equipment significantly.

Additionally, *Cinevoyage* can simulate different types of filmmaking locations in VR. Depending on the given tasks in the scenario, the students will be able to practice in studios with artificial lights or in exterior locations with natural lights, in day and night conditions or under various weather conditions like rain, wind, and snow.

The recent technological developments created also new debates like whether VR may be the end of cinema as we know it. Although the number of VR video productions is increasing every year, VR still does not seem to threaten the classical film and animation productions as we know it. Nevertheless, these new technologies might introduce new filmmaking methods for the future filmmakers. The democratization of technology allows many independent creative people from around the world to design and develop their own short films, animations, games, and various types of applications. We might witness that virtual filmmaking can be one of the main methods of creating cinematic storytelling works in the future (Morozov 2008). *Cinevoyage* can also be considered as an early example that hints what kind of virtual filmmaking tools can be used by future filmmakers. For this purpose, in addition to

the narrative based system with levels, it is considered to implement a free-to-play area within the game, where the student can act as the director of their own scene, where they can choose the equipment, props, actors, coworkers and the style of the material freely in addition to task-based levels.

The content in *Cinevoyage*, which consists of the equipment, props, characters, virtual locations, and tasks, can be extended depending on the development process and the demand in the long term. The design proposal in this article should be considered as a brief glimpse of what *Cinevoyage* is aimed to become at the end of the continuing iterative design and development process.

Methodologies

This section of the article reviews six different design methodologies for educational games, all of which are listed in chronological order from the oldest to the newest. Their most strong and relevant aspects were analyzed and used as helpful resources during the design process of *Cinevoyage*.

Although the FIDGE-model design methodology was proposed by Akilli and Cagiltay (2005), the strategies offered by the researchers in the pre-analysis, analysis, and development phases were beneficial during the research and design process of *Cinevoyage*. The word FIDGE in the title stands for "Fuzzified Instructional Design Development of Game-like Environment" for learning (p. 7). The researchers emphasize the fuzzy logic principle by citing supporting research about it, which basically refers to nonlinear, dynamic approximate and sometimes irrational reasoning of human beings. This approach allowed the researcher to create a design methodology, which is more dynamic and flexible compared to unrealistic strict methodologies, which can be time consuming (p. 3). The researchers determined these following issues in the pre-analysis section, which "addresses the needs of novice instructional designers" (Akilli and Cagiltay 2005, pp. 9, 15); first the instructional designer should decide on her/his target group; second, the instructional designer must decide on the educational subject depending on her/his experience. In the case of *Cinevoyage* this target group can be considered as film and animation students and the subject can be defined as cinematic storytelling. In the third step the instructional designer should make a literature review to investigate whether the selected educational content is suitable for a GBL application. If supporting evidence is found, then designer should specify the pedagogical objectives of the educational game for the selected target group. After this step, the designer should collect data from experts within these fields by asking their opinions and recommendations via primary research tools like surveys or interviews. This step was followed carefully for *Cinevoyage* too. Some of the answers to certain open-ended questions in the survey can be found in the findings section. The designer is also responsible in analyzing the technical aspects of the game development tools; in the case of *Cinevoyage* this step should include both the software and the hardware side due to the technical requirements of VR headsets with various alternatives. The designer should also analyze existing games to decide which genre, platform, and game elements are most suitable for the targeted educational game. As explained in the following sections *Cinevoyage* is decided to be point and click adventure style, narrative VR game with interactive 3D worlds and characters, which is supported with fantastical elements in harmony with real historical anecdotes. Table 1 gives a summary of the analysis and design and development approaches of the proposed methodology.

Second methodology proposed by Göbel et al. (2009) is based on an educational game project in the field of technology-enhanced learning of geography with the aim of harmonizing different features and objectives of the storytelling, learning, and gaming approaches as seen in Fig. 2. The design methodology of the game *80 Days* is based on several principles. The designers used the storytelling as an instrument for suspenseful knowledge transfer by implicating an emotional immersive dramaturgy. The gaming aspects of the teaching material were intended to create a fun,

Educational Virtual Reality Game Design for Film and Animation, Table 1 Summary of the FIDGE model (Akilli and Cagiltay 2005)

Issue	Its property
Participants	All of actively participating learners and experts
Team	Multidisciplinary, multi-skilled, game-player experience
Environment	Socio-organizational, cultural
Process	Dynamic, non-linear, fuzzy, creative, enriched by games' and simulations' elements (fantasy, challenge, etc.)
Change	Continuous, evaluation-based
Evaluation	Continuous, iterative, formative and summative, fused into each phase
Management	Need for a leader and a well-planned and scheduled time management
Technology	Suitable, compatible
Use	By (novice/expert) instructional designers and educational game designers for game-like learning environments and educational games

Educational Virtual Reality Game Design for Film and Animation, Fig. 2 Technology-enhanced learning (Göbel et al. 2009)

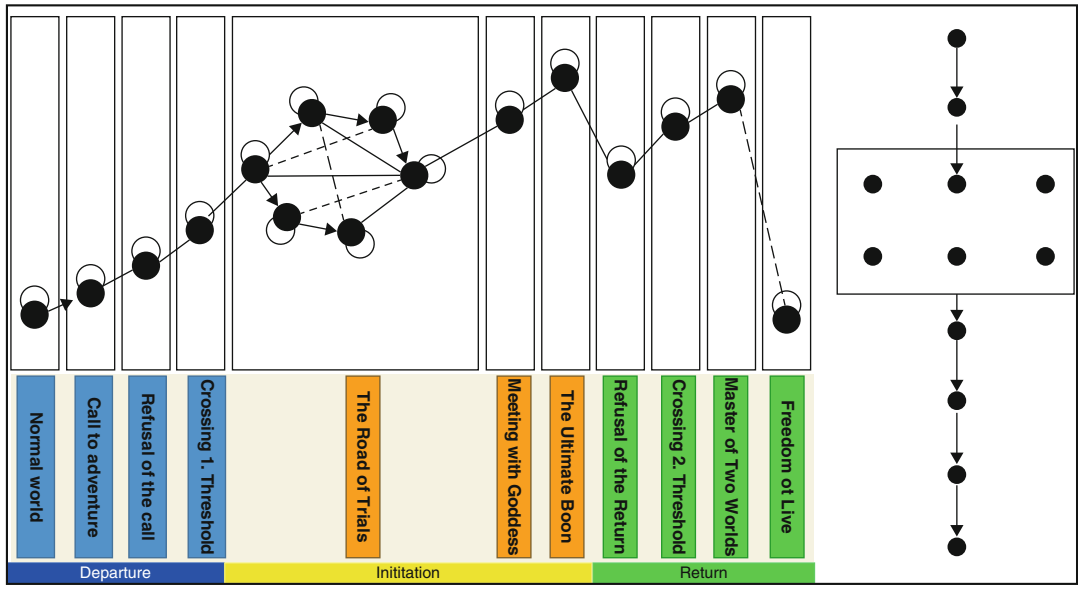
motivational, interactive, and explorative experience. For the learning part, they have emphasized the assessment and learning success by imple menting, motivating, and engaging mechanisms effectively. To prevent a too linear and non-interactive plot-based approach in storytelling, the designers have used the Hero's Journey storytelling model as a template in a flexible way with variations they made in the "The Road of Trials" step for ludological purposes as is seen in Fig. 3 (Göbel et al. 2009). Because of the emphasis on using the Hero's Journey story template in a balanced way, which allows the player freedom to play instead of a boring and too linear story structure, this methodology convinced the researchers and designers of *Cinevoyage* to write the game script in accordance with the same template.

The third methodology study by Marfisi-Schottman et al. (2010) describes the production of a DEGs in seven steps (Fig. 4). For *Cinevoyage* the first three steps are successfully completed. Currently the researchers and designers are working together to evaluate the software solutions for building the mechanics and dynamics of the first play-testable prototype of the game. Once completed, the prototype will be evaluated by scholars according to the GameFlow model (Sweetser and Wyeth 2005) and instructional game design criteria.

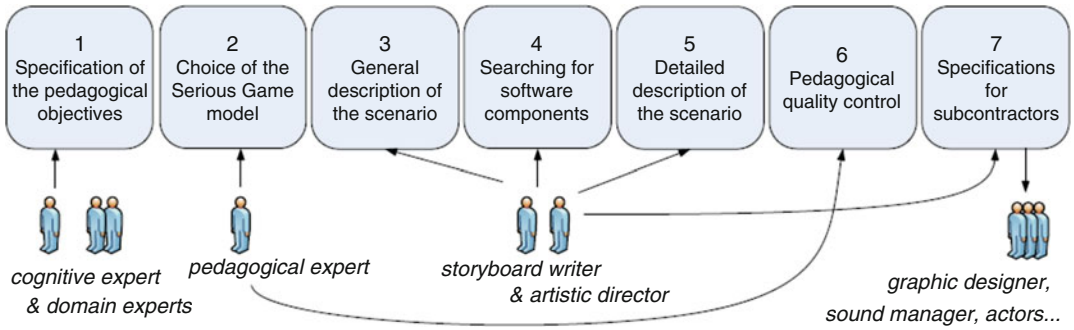
In the fourth study "A New Methodology of Design and Development of Serious Games" Barbosa et al. (2014) propose a new methodology of design and development of educational games, which are enriched with mini-games for having the potential of providing engaging and motivating experiences. This methodology suggests that a main game section with missions and independent tasks like mini games, puzzles, or quizzes serve to transfer knowledge and skill that run in a parallel way without distracting the player too much from the engaging narrative elements (Barbosa et al. 2014, p. 3). In the light of this study, mini-levels are implemented in *Cinevoyage* too (Fig. 5).

The fifth methodology study to design educational games based on interactive screenplays by Prieto et al. (2015) was again emphasizing the importance of creating a detailed scenario in accordance with educational objectives, which will allow the player a fun and emergent learning experience with the support of designed educational game. During the script writing process of *Cinevoyage*, Prieto's methodology functioned as a strong guide (Fig. 6).

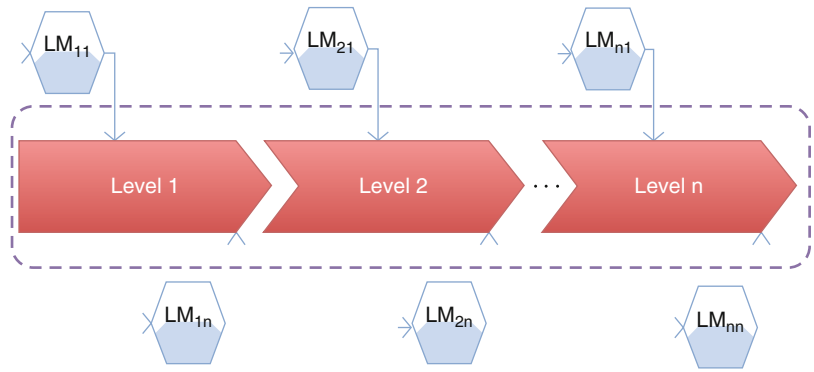
Finally, the dissertation study by Khanana (2016) demonstrates that the old "GameFlow



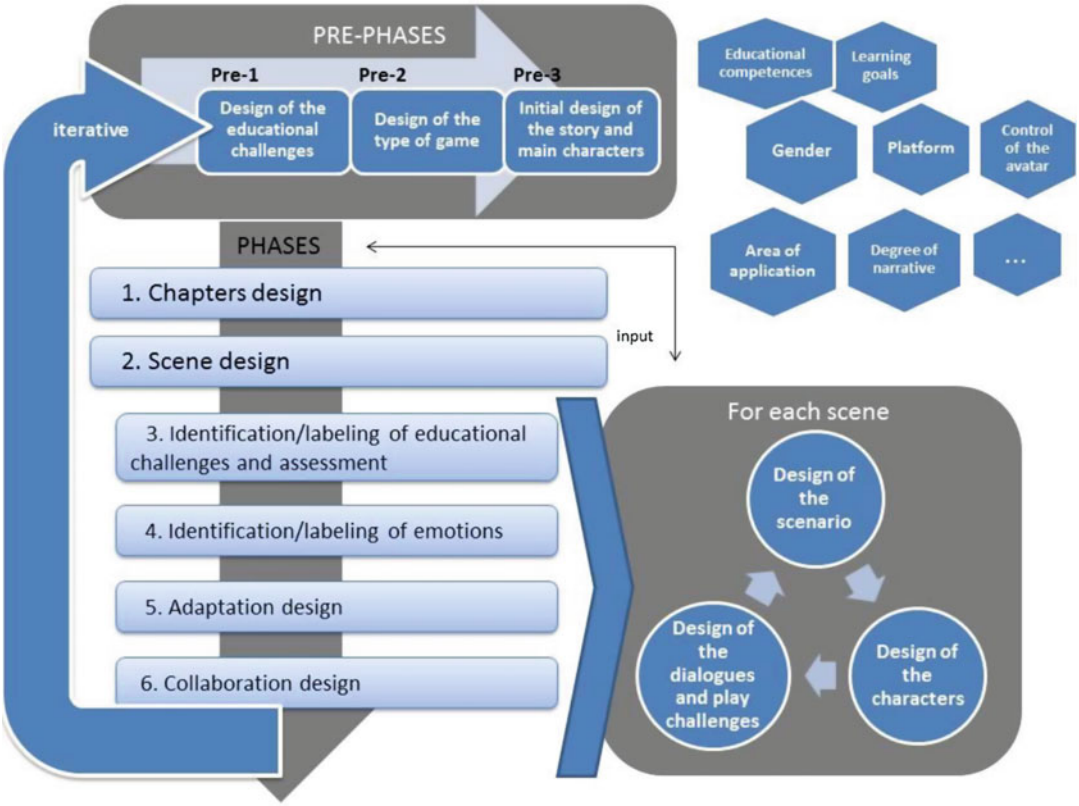
Educational Virtual Reality Game Design for Film and Animation, Fig. 3 Hero's Journey story model (left)/linear and modular story units (right) (Göbel et al. 2009)



Educational Virtual Reality Game Design for Film and Animation, Fig. 4 The seven steps for designing SGs. From tools and methods for efficiently designing serious games (Marfisi-Schottman et al. 2010)



Educational Virtual Reality Game Design for Film and Animation, Fig. 5 Diagram of the methodology; a game with several levels and the learning mechanisms associated to each layer (Barbosa et al. 2013)



Educational Virtual Reality Game Design for Film and Animation, Fig. 6 Methodology based on interactive screenplay (Prieto et al. 2015)

model," which was structured by Sweetser and Wyeth (2005) as a design and evaluation tool for educational games in accordance with the flow theory by Csikszentmihalyi (1990), can still be very effective in the field of educational games. The researcher's main purpose in this study is to propose a simplified, fun design and evaluation methodology for students 7–11 years old. "The gaps of GameFlow model" in this study presents a deep analysis of the eight elements of GameFlow model, which are concentration, challenge, player skills, control, clear goals, feedback, immersion, and social interaction (Khanana 2016, pp. 88–89). Even though *Cinevoyage* is not designed for this young age group the pilot study results by Khanana were instrumental in making the design decisions like the clear goals, good explanations, appropriate challenge levels, nondistractive audiovisual characters, environment and interface, and informative in-game feedback.

Research Design

Gaming Objectives

The objective of the game is to start and complete a journey through the history of cinema, while learning the fundamentals of film and animation making. During the game, the player visits various film sets from different epochs of film history, where s/he interacts with famous filmmakers, who give the player various tasks to proceed further to next levels, where the difficulty but also the reward values increase.

Pedagogical/Educational Objectives

This game is designed as an educational game for film and animation students. Learning occurs by listening, observing, and doing, while the players explore the virtual environments and interact with the characters. The difficulty and the complexity of the knowledge and skills that should be acquired with *Cinevoyage* increase as the player reaches higher levels by completing given tasks successfully.

In *Cinevoyage* the player should be able to reach the following objectives:

To be able to operate the simulated versions of professional cameras, various lighting and grip equipment like dolly, crane, Steadicam, etc., while demonstrating theoretical knowledge on general cinematography

To become more familiar with terms like ISO, shutter speed, aperture, frame per second, depth of field, color temperature, various lenses

To be able to read and understand the following diagrams to complete the tasks:

- Mise-en-scène diagram (showing the movement of the actors)
- Camera diagram (showing the place, angle (s), lens, and movement)
- Lighting diagram (showing the place and type of the equipment)
- Storyboards (showing the framing, shot scales, camera movement)

To be able to work in different filmmaking conditions like in interior and exterior locations with various lighting and weather conditions, which can be both natural or artificial

Victory Conditions

In *Cinevoyage* the player interacts with characters from film history to learn about the task/assignment, which s/he must solve. If the player successfully completes the task, s/he gets immediate feedback from the character and gains the artifact, which enables the player to continue her/his journey to higher levels of the game. As indicated in the "Game Levels" section, the instructor of the educational institute can decide which levels the student should play in relation to their curriculum and learning objectives.

Failure States

If the player cannot succeed in completing a mission, s/he can quit that certain mission and practice with the equipment in a free practice and learning area. The storyline allows to switch to a different mission if the player finds it too difficult. Normally, the player must complete all the tasks to finish the game; however, the instructor of the educational institute can lead their students to play certain levels while skipping some other levels which are more relevant to their learning curriculum.

Another important aspect that needs to be regarded carefully is that the current VR technology can cause health problems like nausea, blurry vision, or headache if played for very long durations (Merhi et al. 2007). This aspect of VR technology is also important to remind the students not to play all levels at once, which might take hours. A typical level of *Cinevoyage* can be passed in 5–20 min. To prevent playtimes longer than 30 min, which can be detrimental to the health of the student, a time limit is also implemented in the design. Accordingly, if the player fails to pass a level in 30 min, s/he can be declared unsuccessful and can only continue after a certain break period.

Game Levels

Research on educational games demonstrates that they are most effective if the educational content is supported with regular lectures (Bonde et al. 2014). Therefore, it is intended to design *Cinevoyage* in such a way that the instructor can choose and lead their students to play certain levels in accordance with their curriculum.

On the other hand, the level design of the game is constructed with references to Hero's Journey story design template. In *Cinevoyage* the player experiences a journey with a guide, which can travel beyond time and space. *Cinevoyage* progresses through several increasingly difficult and complex levels. In each level the player must demonstrate her/his knowledge to perform the given tasks successfully.

If the player successfully completes a level, s/he can travel to the next level. The levels address various learning objectives starting from easy to hard. The player will travel chronologically through levels, which will begin in the early periods of film history around 1900s and will continue till 2017 and beyond. The complete list of levels and the specific educational objectives of each level are briefly summarized in the Tables 2 and 3. Ongoing development phase for a playtestable *Cinevoyage* prototype is going to consist the first five levels. The narrative and visual details of the first five levels are given in the narrative, storyboard, and flowchart sections.

As explained in the methodologies section, the mini-games are also considered as an effective way of knowledge transfer and skill improvement without affecting the game narrative negatively. Therefore, some of the above-mentioned learning objectives will be achieved with the support of mini-games, puzzles, or quizzes.

The Characters

During the gameplay of *Cinevoyage* the player will be able to interact with simulated 3D modeled characters from filmmaking history. In addition to the above listed famous filmmakers, who will both give tasks and instruct the player during the game, there will be additional 3D modeled characters for cast and crew members. As a part of the narrative, the designers decided to use George Méliès as the main mentor of the player, who will be able accompany the player throughout the levels. His character will reflect his abilities as an inventor and magician. His invention *Cinemagica*, which was inspired from actual Méliès short films, functions as a magical inventory box that can keep all kinds of equipment and necessary tools within, will be with the player through all levels.

Game Narrative

As explained in the methodologies section, the main story structure of *Cinevoyage* is based on the Hero's Journey story template, which is claimed to be one of the most occurring story template throughout the human history. As the methodology examples show, Hero's journey is used efficiently in many educational games by allowing the players to go through an emotional journey, while increasing their knowledge and improving their skills. The following storyboard and flowchart sections give a glimpse of the game script for the first five levels.

Storyboard

The storyboard template (Fig. 8), which is used to visualize the first five levels of *Cinevoyage* (Figs. 9 and 10), is a combination of two different templates, which are created by VR developers McCurley (2016) and Leitch (2017), both are based on Mike Alger's presentation with the title

Educational Virtual Reality Game Design for Film and Animation, Table 2 Levels and learning objectives of *Cinevoyage* (0–5)

Level	Movie	Scene	Filmmaker	Learning Objectives
0_Introduction	–	Introduction: Cinemagica	George Méliès	Tutorial for basic mechanics to move, select & interact
1_The Bridge	Photo shooting of the horse (1878)	Movement	Eadweard Muybridge	Fundamentals of photography; exposure, iso, aperture, shutter speed

Level	Movie	Scene	Filmmaker	Learning objectives
6_Retrofuturo	Metropolis (1927)	City miniature	Fritz Lang	Studio shooting, lighting, special effects
7_The Prodigy	Citizen Kane: (1941)	Childhood scene	Orson Welles	Storyboard reading, frame composition, blocking
8_Eastlight	Seven Samurai (1954)	Flag scene	Akira Kurosawa	Frame composition, camera movement
9_The Master	Vertigo (1958)	Vertigo effect	Alfred Hitchcock	Focal length, camera movement
10_Dreamman	8 1/2: (1963)	Asa Nisi Masa	Federico Fellini	Black & white lighting
11_End of Beginning	2001: A Space Odyssey (1968)	Final room scene	Stanley Kubrick	Shot/reverse shot, lighting, colors
12_Houston, we have a Problem!	Barry Lyndon (1975)	Interior, candlelight	Stanley Kubrick	Zoom, depth of field, lighting, lens aperture
13_Depth	Stalker (1979)	Tunnel scene	Andrei Tarkovsky	Composition, depth of field, camera movement
14_Track the Fall	Wings of Desire (1987)	Fall of an angel	Wim Wenders	Shot scales, tracking shot
15_The Bridge	Matrix (1999)	Bullet time effect	Watchowskis	Green screen, special effects, bullet time
16_Location or Not	Dogville (2003)	Introduction	Lars von Trier	*Mise-en-scène,* camera movement
17_Stopmotion	Corpse Bride (2005)	Meeting Emily	Tim Burton	Stop motion, frame composition, lighting
18_Plansequence	Children of Men (2006)	Car scene	Alfanso Cuaron	Advanced plan sequence, scene blocking, shot scales
19_Back to Station	Hugo (2011)	Train crash	Martin Scorsese	Special effects with green screen
20_Resolution	The Revenant (2016)	Church	Alejandro G. Iñárritu	Composition, Imax cameras, crowded scene experience, snowy weather

"VR Interface Design Previsualisation Methods" (2015). As shown in Fig. 7 designing for VR requires to pay attention to certain details like the distances between the objects and the player to provide a comfortable VR experience for the users, which can be planned during the storyboarding process.

The storyboard combines the written information from the narrative script of the game with the visual information that represents a basic version of how the game world, the characters, and the objects should look and how the player is going to interact with them. The storyboard of the first five levels of *Cinevoyage* shown in Figs. 9 and 11 gives the information about where in the virtual world the first-person player will be located; about the famous characters the player is going to meet and interact; about the references to actual movies from film history; about the objects that the player will acquire and the actions that occur when interacting with them; about the vehicles like the Cinetrain, with which the player is going to travel within the game; about the user interface like the camera display; and about the tasks that needs to be fulfilled to pass a certain level.

Flowchart

The flowchart is another important part of a Game Design Document, which functions as a communication platform among the game designers, programmers, and audio-visual asset creators. The flowchart for the first five levels of *Cinevoyage*

Findings

The deep literature review for this study enabled the designers to determine which elements of which design methodologies will be used while designing *Cinevoyage*. After a collaborative work of game designers and instructional designers, the finished Game Design Document of *Cinevoyage* and an online survey was shared with a selected group of people to gather suggestions and recommendations on the general design of the game. Thirty-four out of 92 people, who responded the online survey, claimed that they have experience as an instructor or teacher in film making, video production, photography, and similar branches. Some response examples by these people to the open-ended question "In which ways could you benefit from the educational VR game *Cinevoyage* in your lectures?" can be seen in Table 4.

As is seen Table 4 there are many participants who emphasized the importance of gaining practical experience within the simulated filmmaking environment. Even the participants, who had little or no experience with VR environments can easily imagine how it would benefit the students, when they can play with virtual filmmaking equipment without the fear of making mistakes. Considering the fact many educational institutes cannot afford the professional level film equipment due to the high costs and security risks *Cinevoyage* is

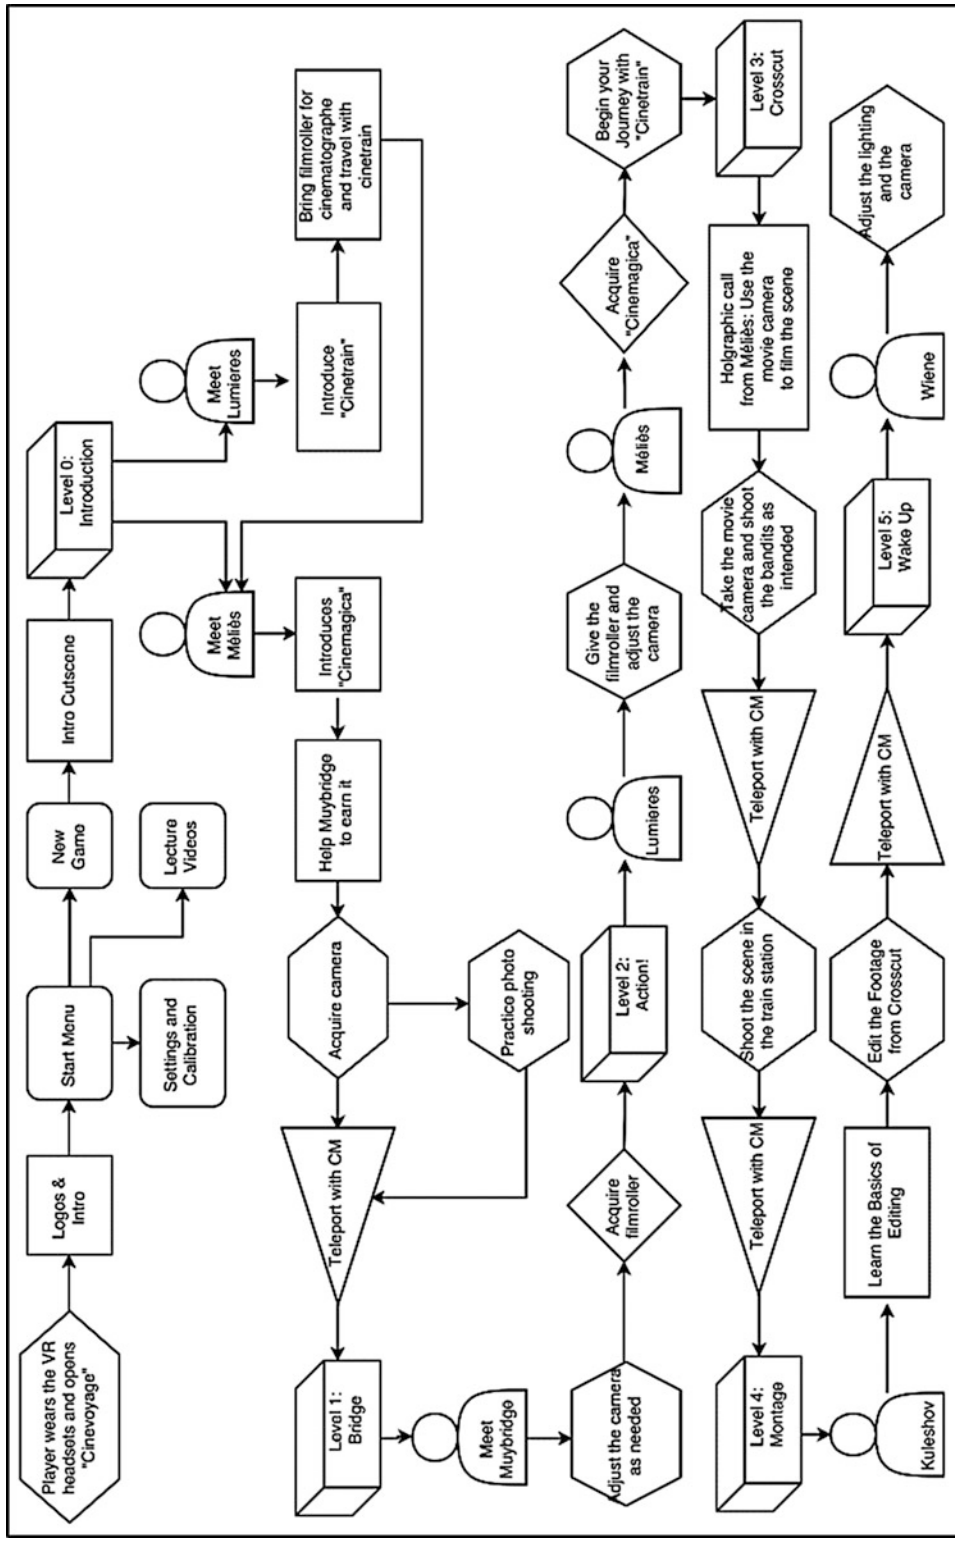
designed with the purpose of enabling the students to work with virtual filmmaking equipment (Sheffield 2001). Additionally, *Cinevoyage* aims to simulate the social aspects of filmmaking too like the interaction with the director or other cast and crew members on a film set, which was considered as an important factor within the survey results (Table 4).

Conclusion and Discussion

According to the study performed by Connolly et al. (2012) the most frequently occurring outcome with educational games was knowledge acquisition and content understanding. The methods of measuring the outcomes of the educational games differed from study to study. The most popular study design for collecting empirical data on knowledge acquisition, motor skills, perceptual and cognitive skills, and physiological outcomes is quasi-experiment, followed by randomized control trials (RCT), surveys, and qualitative designs. On the other hand, to study the affective, motivational, and social outcomes of the games, researchers used mostly surveys even though these were typically to secondary interest (Connolly et al. 2012). To measure the affective and motivational outcomes of the DEGs some researchers used questionnaires. Jennett et al. (2008) used a subjective questionnaire to distinguish immersiveness levels of games based on cognitive involvement, emotional involvement, real-world dissociation, challenge, control, and eye movements. Fu, Su, and Yu's study (2009) found that Sweetser and Wyeth's GameFlow model (2005) can be used effectively in evaluating the motivational features of educational games.



Educational Virtual Reality Game Design for Film and Animation, Fig. 11 Flowchart for *Cinevoyage* (levels 0–5)

Educational Virtual Reality Game Design for Film and Animation, Table 4 Response examples to the survey question "In which ways could you benefit from an educational VR game in your lectures?"

"It could function as a simulation game. If the class that is being taught needs practical skills, it could be used to practice that skill and improve on it without worrying about failure. It would allow the user to learn the skill in a safe, but realistic environment."
"By creating a simulated interactive environment, you can adjust light, distance, lens, camera height, angle etc. *in comparison with various options."*
"Cinevoyage could function as a simulation game. If the class that is being taught needs practical skills, it could be used to practice that skill and improve on it without worrying about failure. It would allow the user to learn the skill in a safe, but realistic environment."
"By creating an interactive environment simulation with this VR game, students can learn quickly to adjust elements like the time, light, distance and lens angle, camera height, angle etc. *in combination with each other."*
"Learning camera and lens, editing, light, and even script writing, can become faster and more fun with the help of a VR game like "Cinevoyage". The burden of collecting visual material for the lecturer would be less with the support of these games. In an interactive virtual film studio, the student can feel like a real cameraman, who takes her/his directions from the director, which would allow her/him to experience theory and the practice at the same time instead of a passive listening experience"

The first working prototype of *Cinevoyage* is planned to be tested within 2018 in some educational institutes. The research and design team is planning to make both similar quasi-experiments with control groups to compare the learning outcomes of cinematic storytelling lectures with the support of *Cinevoyage* versus classical lecture methods. Additionally, the game will be evaluated both by instructors and students according to evaluation surveys and questionnaires like Game Features Test, Instructional Game Survey, and GameFlow model to collect secondary data on motivational and social outcomes, levels of immersion, and engagement of the students during gameplay (Samur 2012).

Cinevoyage is currently under development with a team of script writers, game developers, 3D and instructional designers for room-scale VR platforms with high-end PC support like Oculus Rift, HTC Vive. Additionally, a smaller mobile VR version for platforms like Samsung Gear VR and Google Daydream are in consideration, which are planned for quick prototyping sessions. As can be seen within this article *Cinevoyage* has a very wide scope and it can be expanded as the demand occurs. Currently, funding opportunities for a sustainable design and development process of *Cinevoyage* are being investigated by the researchers too.

Moreover, as the study by Zhang and Zhao (2017) exemplifies successfully that AR is also very promising to support education. Therefore, the design team of *Cinevoyage* is also experimenting with technologies like ARkit for Apple devices and ARCore for Android smartphones and how they can be used for cinematic storytelling education too.

EEG as an Input for Virtual Reality

Oğuz Orkun Doma
Architectural Design Computing, Istanbul Technical University, Istanbul, Turkey

Synonyms

BCI, brain–computer interface; EEG, electroencephalography; Virtual reality

Definitions

Brain-computer interfaces (BCI) use electrophysiological measures of brain functions to send inputs to a computer from a new non-muscular channel (Wolpaw et al. 2002). In this entry, the use of electroencephalography (EEG) is introduced as a BCI input for virtual reality (VR). A VR mini-game is developed to showcase the use of EEG as an input in VR. With EEG, using the predefined brainwave patterns that are defined via EEG as a set of commands, users can interact with their environments in VR dynamically, through the changes in their emotional mood and concentration. This does not only introduce an alternative input for VR, in which the physical body's integration is somewhat restricted due to the technological limitations, but also enables authentic digital realm experiences which would be impossible in the physical world.

Introduction

Ability to move objects with the mind has always been an intriguing subject for humans. The idea of being able to interact with our environment without direct physical contact has been at the center of the works of fiction as well. The concept of *Force* in Star Wars film series is an excellent example of it, which helps certain characters who can use it to perform telekinesis (Bouzereau 1997). Despite that any parapsychological effort has failed to show any credible real-world evidence for the practice of telekinesis, which is based on illusion, science has finally developed new brain–computer interface (BCI) technologies that allow humans to interact with their environment solely concentrating with their minds. Electroencephalography (EEG) is one of these BCI technologies. EEG is monitoring the electrical activity of the brain, measuring voltage fluctuations from electrodes placed on the scalp (Fisch and Spehlmann 1999). EEG has been studied widely as a part of neurology, psychology, and marketing studies, and it is commonly used in the industry fields like education, rehabilitation, entertainment, and user experience design (Wolpaw et al. 2002; Finkelstein et al. 2010; Mulert and Lemieux 2009; Friedman 2015). With the recent developments in wearable technologies and EEG headsets, they became more affordable and available for casual end users. Therefore, EEG is increasingly used as a swift and unique BCI input, which enables user interaction via brain waves or "thoughts" in virtual environments (Li et al. 2017).

VR and EEG

Virtual reality is a different realm where all the experience takes place beyond the physical realm. Thanks to the current persuasively photorealistic CGI technologies, increasing processing speed, improved refresh rate on displays, and affordability of the user hardware, virtual reality has been a popular subject once again (Jerald 2015). Every

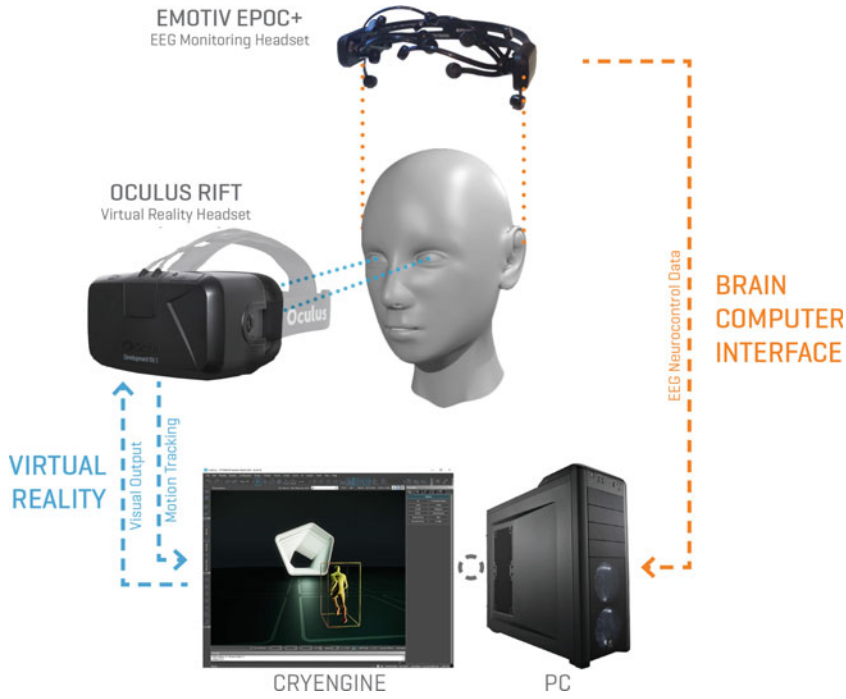
day more and more VR headsets are being sold, and more VR content is being developed. Therefore, VR is far beyond being an experimental technology but becoming an essential part of how we interact with the digital realm. Several universities and laboratories have used EEG as a control input for virtual environments and video games successfully (Lecuyer et al. 2008). Using EEG in VR makes the experience even more immersive.

Transferring the user's inputs and movements to VR as comprehensive as possible ensures an immersive experience. These inputs are mostly within the possibilities of what humans already have in the physical world: movements, controllers, haptics, eye tracking, and vocal commands, to name a few. This gap between physical and virtual adds to the ambiguous manifold of reality and virtual realities. This critical duality also leads to new opportunities, which weren't available before the digitally manufactured realities. Virtual does not necessarily need to be an epigone of the reality. As Baudrillard put it, simulation creates its own hyperreality, beyond its referential reality (Baudrillard 1999). By using the authentic new opportunities of this hyperreality, it is possible to represent the human body in the virtual space in novel ways that it cannot be represented in the physical space and enable novel interactions that are not possible in the physical reality. It also delivers more enhanced inputs faster into the virtual environments (Li et al. 2017). While bodily existence in VR is a critical one, using brain waves as an interface between the brain and the virtual space will enable manipulation, interpretation, and recreation of that space only using the brain itself.

In the project that is mentioned in this article, EEG was used to create a dynamic interaction via neural controls for a VR video game experience. The players can dynamically interact with the VR environment with the changes in their emotions and mental concentration.

Method

This project makes use of two technologies: VR and EEG. The player experiences the VR video



EEG as an Input for Virtual Reality, Fig. 1 Brain-Computer Interface (EEG) and Virtual Reality pipeline of the project

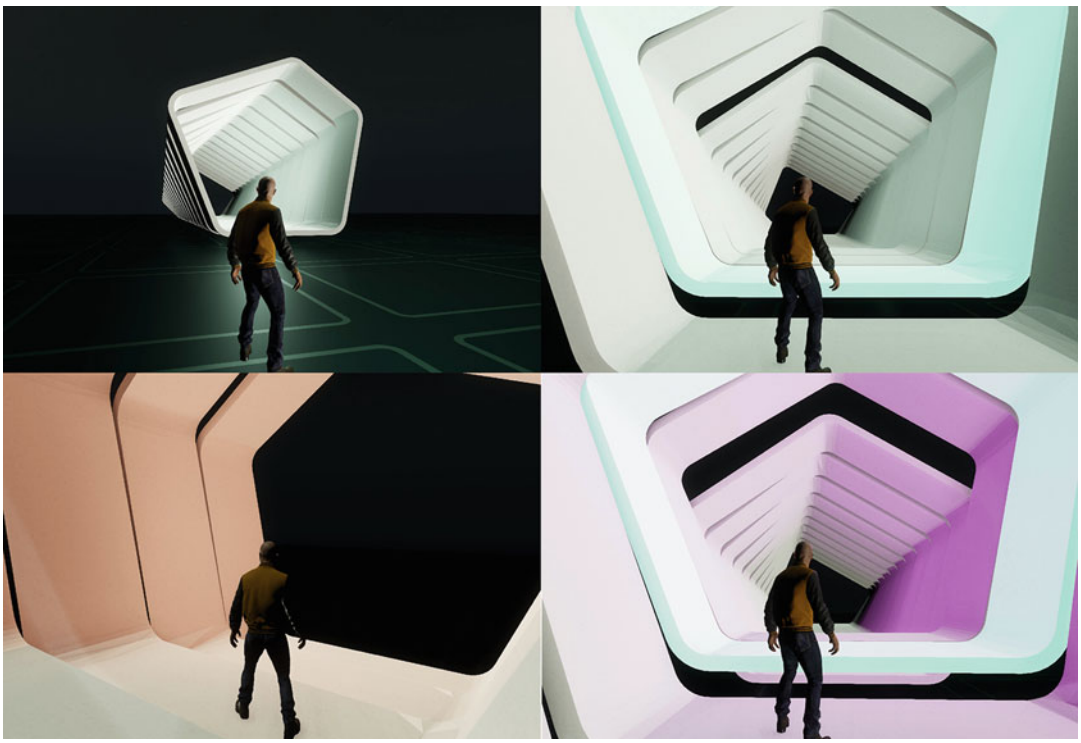
game created in CRYENGINE via Oculus Rift VR headset. The core mechanic of the designed gameplay is simple; the player walks through a segmented tunnel, trying to elevate each segment to form a flight of stairs to reach a higher platform. Meanwhile, the interior lighting of the tunnel changes based on the player's emotions (Fig. 1).

Emotiv EPOC+ EEG headset monitors the player's brain activities and digitizes it as a computer input. Emotiv's dedicated software *EPOC Control Panel* enables certain neural patterns, which the player needs to define it beforehand, to be read as an input for the VR video game. In this project, the players define EEG commands such as push/pull and resize objects in EPOC Control Panel. As seen in Fig. 2, these commands are used as controller inputs by CRYENGINE. *EPOC Control Panel* also streams the excitement, engagement, and meditation levels of the player to CRYENGINE, which is converted into an RGB color for the environmental lighting in the VR game.

In a previous study, users wearing Emotiv EEG headset were able to drive an automobile with EEG commands (Göhring et al. 2013). Therefore, the precision of EEG is considered to be well enough as a controller input for the VR game.

Results and Conclusion

Using EEG as a brain–computer interface for VR provides a new range of unique possibilities and interactions, which would be impossible in the physical world. Making a user move an object with EEG in the physical world would require a lot more effort than moving some object in a video game in VR. Also, wearing EEG headsets is not very fashionable yet, but it is less bothersome when the user is already tethered in



EEG as an Input for Virtual Reality, Fig. 2 The players elevate each segment by concentrating on the push/pull commands they have defined

VR. Considering the existing bodily integration and movement limitations of virtual reality technologies, figuratively connecting the brain directly to the computer by the use of EEG as an input for VR looks very promising for the future applications.

DLC

Definition

Emotion in games – a feeling such as happiness, love, fear, anger, or hatred while a person is playing a computer game.

DLC – downloadable content, often called DLC, is extra content made for a game after release. It can be given out freely or monetized.

Introduction

Emotion is how we feel and how connected we get to someone or something. In life we cry over the ones we have lost or if we are mad we will be angry at life or at someone. Believe it or not, some people who play video games can get emotional on a character's death or dying so much that they want to break the game controller. (Isbister, 2016)

Character growth is what most players like to see in an intense story-driven game. Some examples of games that show emotion well are *Halo, Mass Effect, Red Dead Redemption, Call of Duty, and Gears of War.* These games present great character growth but they also let their favorite characters die. For example, Dom, in *Gears of War*, is the brother in arms who dies in the third game, sacrificing himself to save his friends and to be with his family. In *Call of Duty*, many memorable likable characters die, including Soap, Ghost, Sandman, Harper, and Mason. In *Mass Effect*, we can build our own character from body and facial features, and transfer them to other mass effect games so we can continue the adventure. However, the character ends up dying at the end of the third game, causing trauma for some players.

Here are some examples of emotion in games: (Freeman, 2004; Yannakakis & Paiva, 2014)

Emotion: Fear.

A player is playing a game and hears sounds that cannot be explained, shadows in the distance, or have a restrictive camera view.

Emotion: Joy.

A player gets a gun or armor piece that is extremely valuable as a reward for completing a difficult trial; they are probably going to be filled with joy.

Emotion: Panic.

Games can induce panic in ways that are tied to story in gameplay. The second chapter of *Super Paper Mario* has the player exploring a mansion for Merlee, an important character. After a few mishaps while exploring the estate, including getting thrown in a dungeon by Merlee's assistant, Mario and company search the basement to find an imposter Merlee. While some players could assume from context clues that Merlee's assistant

was the imposter, players could not predict that the assistant, who calls herself Mimi, would reveal her true form by having her head spin around her neck and sprouting spider legs. From here, Mimi chases Mario throughout the basement until he can find the real Merlee. Despite having a creepy appearance, Mimi is also threatening: She is invincible, can shoot projectiles, and can follow players through doors. This scenario changes a platformer where a character can take their time into a situation where players need to think fast to solve puzzles to get to the end of a maze.

Emotion: Frustration.

Some games are designed to make the player frustrated with difficult challenges. Some players play for the clout of being able to make it through a difficult level.

Emotion: Sadness.

A game that does this well is *Destiny 2* with its DLC, *Forsaken*. In the base campaign, the player gets the feeling of hopelessness. The central hub that was enjoyed in the main game is suddenly under fire and can no longer be accessed, aiming to make the player feel uncomfortable.

Emotion: Vengeance.

Vengeance is not always so predictable. In Forsaken, a main character from the Vanguard, Cayde 6, dies by the hands of Uldren Sov. The goal from thereon out is to kill Uldren Sov by hunting him down the entire campaign. The player does get a feel for vengeance but the hole that Cayde 6 has left for the player will never be repaired.

Emotion Driven by Audio and Music.

The emotional impact of audio and music cannot be understated. (Williams & Lee, 2018) Combining images with audio enhances the impact of a multimodal experience during gameplay. Unlike traditional composition such as film music, game music mirrors the nonlinear narrative of gameplay. Player-dependent actions can change the narrative and thus the emotional characteristics required in the soundtrack. Video games uses various techniques such as algorithmic composition, automated emotion matching from biosensors, motion captures, emotionally targeted speech synthesis and signal processing, and automated repurposing of existing music matching the expected emotion of the players.

Affect; Music

Definition

Video game audio is more challenging in many regards than traditional linear soundtracking. Soundtracking can enhance the emotional impact of gameplay, but in order to preserve immersion, it is important to have an understanding of the mechanisms at work when listeners respond to audio emotionally.

Introduction

Video game soundtracking presents a number of unique challenges in contrast to traditional linear soundtracking (e.g., in television or film). Many solutions are in use to address the most common problem: dynamic soundtrack creation in response to gameplay action, but these often approach the problem from the point of view of, for example, procedural audio techniques (Collins 2009). One of the major reasons to include soundtracking is to enhance the emotional response of the player, for example, to accentuate danger, success, failure, and other elements of gameplay (Berndt 2011). Depending on the type of game, there may be established musical grammars to convey such things, and thus emotional congruence is vitally important in maintaining player immersion (Arsenault 2005). Defining what we mean by "emotion" is important here, as perceptual science often refers to a number of synonymous terms (including mood and affect). These are sometimes distinguished between according to the length and specifics of the feeling, with mood being longer lived, for example (Williams et al. 2014). If a player is in danger, do they feel threatened, excited, afraid, or angry? Are any of these terms quantifiable (is there a medium level of fear that might be increased as the level of danger in the game increases?) and are they distinct and in a linear relationship to one another (if fear increases, will excitement also increase?)? These are difficult questions to answer but of vital importance for the game sound designer if successful emotionally congruent soundtracking is to be achieved. For our purposes we will consider terms including affect, mood, and emotion as being interchangeable, and rather than referring to affective states or moods, we will refer simply to emotion or emotional responses.

How Is Emotion in Music Measured?

There are established methods for evaluating emotional responses in traditional psychology and cognitive sciences (Schubert 1999). These can be, and have been, adapted to the evaluation of emotional responses to music. A popular model is the two-dimensional (or circumplex) model of affect (Russell 1980). This plots positivity (valence) on a horizontal axis and activation strength (or arousal) on the vertical axis. Thus, a player state with high valence and low arousal might be described as calm, peaceful, or simply happy. This approach has the advantage of being able to quantify the emotional response – we can have a sliding scale for both axes and perhaps a particular emotional coordinate for a player at a given point in the narrative of the game. This approach also facilitates some direct mapping to a given soundtrack which matches the player state. However, this type of model is problematic. For example, let us consider a state which is very negative and also very active (low valence and high arousal). How might a player in such a condition be described – afraid? Or angry? Both are very active, negative states, but both are quite different types of emotional response. So three-dimensional models of emotion have also been proposed, for example, including dominance as a third axis (in which case, *afraid* might be a passive response, at one end of the scale in the third axis, and *angry* would be the dominant response at the opposite end of the same scale) (Mehrabian 1996). This three-dimensional model and models like it have also come under criticism when adapted to use with musical stimuli, and multidimensional, music-specific models have recently been used (Scherer 1995).

Challenges and Future Technology

One of the most important issues when considering emotional congruence in video game soundtracking is the distinction between an emotion which the music *communicates* and an emotion which the player actually *feels* (Gabrielsson 2002). Imagine that the player is in a part of the narrative which requires generically happy sounding music. The tune which is selected by the audio engine might resemble circus music, but in this particular case, the player has a phobia of the circus and in particular of clowns. The music may then create the opposite of the intended

emotional state in the player. Similarly, there is a growing body of evidence which suggests that when sad music is played to a listener who are in a similar emotional state, the net effect can actually be that the listener's emotional response is positive, due to an emotional mirroring effect which releases some neurosympathetic responses (Molnar-Szakacs and Overy 2006). There is some research suggesting that music has the power to be perceived as a sympathetic listener and to make people in negative emotional states feel "listened to." Therefore, giving generically sad music to the player at a particular point in the narrative might also be inappropriate. Beyond this, almost everyone has slightly different tastes in music, including preferences for certain genres, performers, and even specific songs (Kreutz et al. 2008). These individual differences are very challenging for the game audio designer to account for, but the greatest challenge remains that of adaptability to nonlinear narrative changes (changes under the control of the player or other game agents). Early solutions such as looping material can become repetitive and ultimately break player immersion. Branching strategies, wherein different music cues are multiplexed at narrative breakpoints, can drastically increase the compositional complexity required in the audio design strategy (Lipscomb and Zehnder 2004). An alternative might be to apply procedural audio techniques, which have been used with varying degrees of success in game sound effect sequencing and design. However, for music tasks, the computational cost involved in procedural generation can be large – for example, if long sequences of pre-rendered audio are required for particular narrative sequences with various nonlinear properties, in response to gameplay and intended emotional state. Such solutions can also require a great deal of compositional complexity (with only limited savings in this regard over branching strategies) but have been used successfully in some instances, for example, LucasArts *iMuse* system (Strank 2013) which was a dynamic music streaming system which initially used MIDI files with varying degrees of transformation to imply characters and emotional states. This system was used to accompany role-playing games (including the *Indiana Jones* series and, perhaps most famously, the *Monkey Island* series of games). iMuse implemented two now commonplace solutions, horizontal re-sequencing and vertical re-orchestration, both of which were readily implementable due to the use of MIDI orchestration as a structural representation of the music soundtrack, rather than a definitive (i.e., recorded and rendered) digital audio file.

In the future, we might see an optimized solution, combining machine learning approaches to composition with an individual's own selection of music or the use of biophysiological measures of emotion to manipulate a soundtrack to best maximize the intended, induced emotional response in an individual gamer on a case-by-case basis. These solutions sound far-fetched at the time of writing, but due to the increase in wearable biosensing technology, and the ever-decreasing cost of more complicated associated technology (facial recognition, electroencephalography, galvanic skin response), such technology may well become commercially viable in the world of game audio soon.

Definition

Emotion-based 3D CG character behaviors are the various actions of intelligent agents with emotions in virtual space. This article especially focuses on the intelligent agents communicating with a human, i.e., an agent as an intelligent user interface with abilities to understand human's emotions. This topic contains diversified research fields: *Intelligent Agent*, *Intelligent Virtual Environment*, and *Affective Computing*.

Introduction

Nowadays, the user interface connecting a human to a computer has come to play a more important role in our daily life. Since the user interface takes multimodal styles, such as voice input/output interface and haptic feedback interface, many researches about *Human Computer Interaction* (HCI) (Wong and Horace 2008) have been actively made. Especially, *Intelligent User Interface* (IUI) (Sullivan and Tyler 1991) which can sophisticatedly interact with a human by using *Artificial Intelligence* (AI) technologies or *Computational Intelligence* (CI) technologies has a role to promote human-computer communications. IUI with an ability to understand human's emotions enables to make their relationships more closely and friendly. On the other hand, the researches of *Intelligent Agent* in a virtual environment also have developed with AI and *Artificial Life* (AL) fields. Non-Player Character (NPC) in a video game is an appropriate example as the intelligent agent. This article focuses on researches about an intelligent agent with feelings and emotions as IUI and introduces theories and technologies related to them.

This article is organized as follows. The next section introduces popular researches about emotional theories and emotion models which are frequently referred by *Affective Computing* (Picard 1995) researches. Then, in the Section of "Intelligent Agents with Feelings and Emotions", several related researches about intelligent agents with feelings and emotions are introduced, e.g., Intelligent Virtual Environment (IVE), emotion recognitions, and so on. Afterward, Section 4 explains future visions

and state-of-the-art technologies about *Affective Computing* researches. The section especially focuses on Deep Learning technologies, which is one of the hot topics in AI and CI fields, and considers its possibilities to be adopted to the intelligent agent. Finally, Section 5 concludes this article.

Emotion Theories and Emotion Models

Emotion theories and emotion models are discussed from viewpoints of various research fields. One of the dominant theories is *Discrete* Emotion Theory. The theory considers emotions as discrete elements. One of the well-known researches in this theory is Ekman et al. (1982). They classified human's emotions into six discrete categories, *Joy*, *Sadness*, *Anger*, *Fear*, *Disgust*, and *Surprised*, based on their facial expression researches. As another model of categorizing emotions, Parrott represented emotions as a tree-structured list which consists of three types of categories: Primary emotion, Secondary emotion, and Tertiary emotions (Parrott 2001). The upper image in Fig. 1 describes the list. Another dominant theory is *Dimensional* Emotion Theory. The theory considers emotions as a combination of several psychological dimensions. Therefore, each emotion is not separated but continuously allocated on two or three dimensions. Posner et al. introduced emotions represented as a two-dimensional circular space which has two axes of *Arousal* and *Valence* (Posner et al. 2005). Emotion states are allocated in the circular space according to the values of the axis. The left-lower image in Fig. 1 depicts a circular style model. Plutchik's wheel of emotions is a popular example of the three dimensional emotion model (Plutchik 2001). The wheel model is described as the right-lower image in Fig. 1. He defined eight primary emotions. Each emotion has an opposite emotion: *Joy-Sadness*, *Trust-Disgust*, *Fear-Anger*, and *Surprise-Anticipation*. The primary emotions are allocated on the circle by degrees of similarity. Emotions allocated outside of the circle are mixture emotion of each neighbor primary emotions. The vertical dimension describes intensity of the primary emotions: the upper side means a high intensity state of a primary emotion and the lower one means a low intensity state of it. As different emotion theories from these, there are another approach to represent emotions as the relationship between a physical response and mental feeling. Several different theories, e.g., James-Lange's theory, Cannon-Bard's theory, and Schacter-Singer's Two-factor theory, are in the concept but the theories would be able to be divided into two concepts: Appraisal Theory (Emotion Drives Behavior) or Constructivist Theory (Behavior Drives Emotion). In the case that a human encounters a bear, in Appraisal Theory, he trembles because he felt fear; meanwhile, in Constructivist Theory, he feels fear because he trembled. The OCC (Ortony, Clore, and Collins) model represents these relationships between emotions and behaviors (Ortony et al. 1998). Because the model is possible to predict an appropriate emotion in given situations, the most of researches about agents' behaviors use this model for implementing agents' emotion and behavior models. Figure 2 depicts the OCC model. The model describes a hierarchy structure and 22 types of emotion categories. The hierarchy has three branches about *Events*, *Agents*, and *Objects* in its situation. The model explains why an emotion occurs from the situation by retrieving these branches according to its situations. For example, consider a situation where there are two agents in a virtual environment, i.e., agent A and agent B, and predict an appropriate emotion of agent A in the following situations.

- Find a wallet that had been lost (*consequences of events*)
- The wallet is a thing of agent B (*consequences of others*)
- Agent B smiles (*desirable for other*)

In these situations, the OCC model built-in agent A indicates *happy-for* agent B.

These introduced emotion theories are used for constructing emotion models for intelligent agents. The emotion models become a trigger to cause the agent's behaviors.

Primary Emotion	Secondary Emotion	Tertiary Emotions
Love	Affection	Adoration, Affection, Love, Fondness, Liking, Attraction, Caring, Tenderness, Compassion, Sentimentality
	Lust	Arousal, Desire, Lust, Passion, Infatuation
	Longing	Longing
Joy	Cheerfulness	Amusement, Bliss, Cheerfulness, Gaiety, Glee, Jolliness, Joviality, Joy, Delight, Enjoyment, Gladness, Happiness, Jubilation, Elation, Satisfaction, Ecstasy, Euphoria
	Zest	Enthusiasm, Zeal, Zest, Excitement, Thrill, Exhilaration
	Contentment	Contentment, Pleasure
	Pride	Pride, Triumph
	Optimism	Eagerness, Hope, Optimism
	Enthrallment	Enthrallment, Rapture
	Relief	Relief
Surprise	Surprise	Amazement, Surprise, Astonishment
Anger	Irritation	Aggravation, Irritation, Agitation, Annoyance, Grouchiness, Grumpiness
	Exasperation	Exasperation, Frustration
	Rage	Anger, Rage, Outrage, Fury, Wrath, Hostility, Ferocity, Bitterness, Hate, Loathing, Scorn, Spite, Vengefulness, Dislike, Resentment
	Disgust	Disgust, Revulsion, Contempt
	Envy	Envy, Jealousy
	Torment	Torment
Sadness	Suffering	Agony, Suffering, Hurt, Anguish
	Sadness	Depression, Despair, Hopelessness, Gloom, Glumness, Sadness, Unhappiness, Grief, Sorrow, Woe, Misery, Melancholy
	Disappointment	Dismay, Disappointment, Displeasure
	Shame	Guilt, Shame, Regret, Remorse
	Neglect	Alienation, Isolation, Neglect, Loneliness, Rejection, Homesickness, Defeat, Dejection, Insecurity, Embarrassment, Humiliation, Insult
	Sympathy	Pity, Sympathy
Fear	Horror	Alarm, Shock, Fear, Fright, Horror, Terror, Panic, Hysteria, Mortification
	Nervousness	Anxiety, Nervousness, Tenseness, Uneasiness, Apprehension, Worry, Distress, Dread

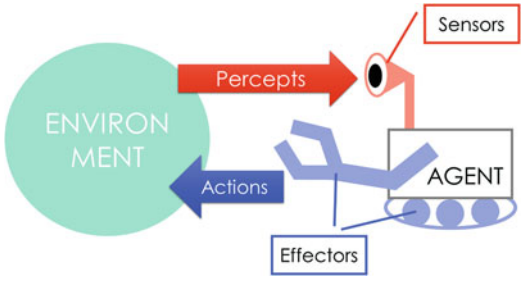
Intelligent Agents with Feelings and Emotions

The term of *Intelligent Agent* is defined in various interpretations around AI and CI fields. According to the book written by Smith et al., Kasabov in 1998 defined the characteristics an intelligent agent should exhibit as followings (Smith et al. 2009).

- Plan, learn, and improve through interaction with the environment (embodiment)
- Adapt online and in real time
- Learn quickly from large amounts of data
- Accommodate new problem solving rules incrementally
- Have memory-based exemplar storage and retrieval capacities
- Have parameters to represent short- and long-term memory, age, forgetting, etc.
- Be able to analyze itself in terms of behavior, error, and success
- Have the ability to represent and reason over knowledge
- Have "social intelligence" for effectively interacting with other Artificial General Intelligent agents

Russell and Norvig also defined an agent as *anything that can be viewed as perceiving its environment through Sensors and acting upon that environment through Effectors* (Russell and Norvig 1995). The agent model is described in Fig. 3. In the case of a humanoid robot, the *Sensors* would be eye-cameras for recognizing things and ultrasonic sensors for detecting distances from other things and the *Effectors* would be arms and legs for influencing their environment which would be real-space. This article treats *Intelligent Agent* as a software program which has ability to autonomously behave according to changing conditions in its environment including *Virtual* and *Real* space by using the *Sensors* and the *Effectors*. In the virtual space, intelligent



Emotion-Based 3D CG Character Behaviors, Fig. 3 Russell's and Norvig's intelligent agent model

agents perceive information from their virtual environment and behave according to their purposes. Such virtual environment containing intelligent agents is called Intelligent Virtual Environment (IVE). Aylett and Luck defined IVE as *combination of intelligent techniques and tools, embodied in autonomous creatures and agents, together with effective means for their graphical representation and interaction of various kinds* (Aylett and Luck 2000). Namely, IVE is a study field of merging Virtual Reality (VR), AI, and Artificial Life (AL) fields. As a research about agents with feelings and emotions in IVE, Liu1 and Pan introduced an emotion model of 3D virtual characters in IVE (Liu and Pan 2005). The virtual characters have the ability to perceive current environment conditions in their virtual space, e.g., a forklift is closing to them, and they can express their emotion by their body pose movements and their facial expressions. A lot more IVE researches and applications appear in the survey paper written by Aylett and Cavazza (2001). Researches for constructing an emotion model to operate the *Effectors* are important theme to implement an intelligent agent. Egges' approach can be helpful to build the emotion model and the agent's behaviors as the *Effectors* (Egges et al. 2003). The authors provided a generic model for personality, mood, and emotion simulation for conversational virtual humans. The personality and emotion model was developed based on the five personality factors, i.e., *Openness*, *Conscientiousness*, *Extraversion*, *Agreeableness*, and *Neuroticism*, and one good-bad mood dimension. Additionally, the authors used the 24 emotions based on the OCC model to express agent's emotions by using facial animations. The model was applied to their prototype application which has a dialogue system and a talking head with synchronized speech and facial expressions. As researches for the *Effectors* which express agents' feelings, Raouzaiou's facial expression research is useful (Raouzaiou et al. 2002). Raouzaiou et al. defined basic facial expressions of six emotions based on the Ekman's emotion theory using Facial Animation Parameters of the MPEG-4 specification. Egges and Thalmann's research about an emotion model and body animations with its emotions for a 3D character can be available to implement intelligent agents in virtual environment (Egges and Thalmann 2005). The authors introduced an idle motion engine which was adopted 2D emotion space with activation-evaluation axis and can generate realistic looking animations according to its emotional state. Several researches tried to develop an authoring system to build these emotion model and agents' behaviors. BAAP (Behavioral Animation Authoring Platform) developed by Li et al. is one of such systems (Li et al. 2010). They implemented agent's emotion model by using 2D emotion model which contains six emotions, *Happiness*, *Sadness*, *Anger*, *Fear*, *Surprise*, and *Disgust*, and agent's behavior was controlled by a *Behavior Tree* in which a leaf node represents a behavior of the agent. The tree structure was implemented based on the OCC model. The authoring system can customize an agent's personality by operating an interface of the behavior tree. They introduced a story scene as an experimental result in where two different stories are generated by changing agents' personalities. As another approach, Loyall et al. (2004) developed an authoring system which can build a 3D character's personality including its emotion. The system controls their 3D character by script languages. Popescu et al. developed an emotion engine for a NPC in a video game (Popescu et al. 2014).

By changing the perceptive target of the *Sensors* from virtual-world to real-world, the intelligent agents can be adopted to IUI. Namely, the agent can percept humans' behaviors such as

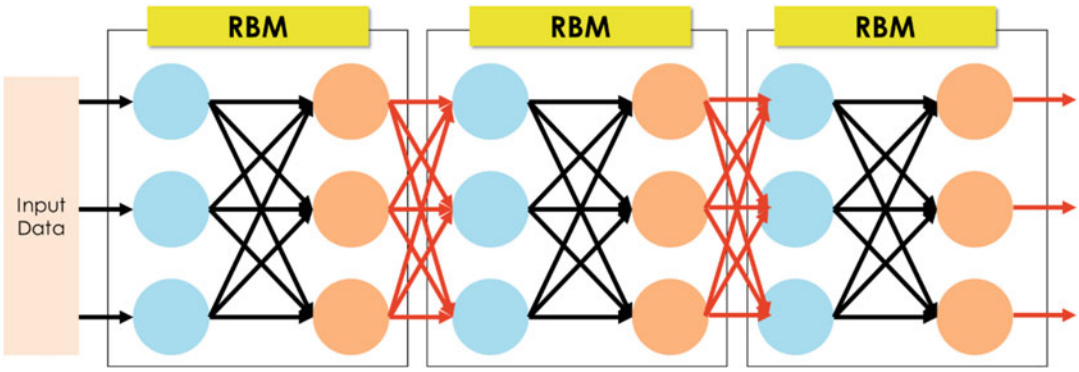
facial expressions, conversations, and gesture poses, and act in the virtual-world according to the real-world conditions by operating the *Effectors*. In a case of the intelligent agent with feelings and emotions as IUI, the functionalities of the Sensors and Effectors can be handled as those of emotion detections and recognitions from humans' behaviors. Azcarate's recognition method classified seven emotions, *Happy*, *Surprised*, *Angry*, *Disgusted*, *Afraid*, *Sad*, and *Neutral*, from facial expressions by using Naive Bayes Classifier (Azcarate et al. 2005). Castellano et al. recognized human emotions from gestures (Castellano et al. 2007). They focused on a velocity, acceleration, and fluidity of the hand's barycenter in continuous gestures. As a research of intelligent agents as IUI, Kaneko and Okada introduced a system for the agents who understand human emotion and express the emotion by facial expression (Kaneko and Okada 2014). The agent can receive voice input data from a microphone and convert it to text data. The text data was interpreted by an emotion word database and the agent express the emotion as a facial expression. In video game fields, such Affective Computing research is called *Affective Gaming* (Gilleade and Dix 2005). Bacivarov and Corcoran tried to apply facial expressions to video games (Bacivarov and Corcoran 2009). A lot more researches and applications about *Affective Gaming* are summarized in the survey paper written by Kotsia et al. (2013).

Future Visions and State-of-the-art Technologies

In the future, intelligent agents with feelings and emotions as IUI will play increasingly important roles to connect a human and a computer in various application fields. In Virtual Reality (VR) fields, we might spend our daily life for in IVE by using a head mount display and haptic devices. A 3DCG character as an intelligent agent, in the situation, will become a helper for psychological therapies and physical rehabilitations. Augmented Reality (AR) and Mixed Reality (MR) can be available in another field for the intelligent agents to play an active role. The agents might be able to become a navigator on maps and a supporter for our learnings. We can feel these possibilities of intelligent agents from the survey paper of Virtual Learning Environment (VLE) by Pan et al. (2006). Although it is different from VR, the concepts of the intelligent agents and method to build emotion models can be adopted to *Reality* field, e.g., robotics technology. A robot which has sensors used to understand humans' emotions and abilities to express his/her feelings is one of the ideal intelligent agents and can become a good partner for human beings. The affective robot research of Breazeal shows us the possible future visons (Breazeal 2003).

Because IUI is closely related to AI and CI fields, in the future as well as current situation, the researches and technologies about intelligent agents as IUI will evolve with these fields. In AI and CI fields, these days *Deep Learning* (Deng and Dong 2013) becomes one of the hot topics. Deep Leaning is a set of machine learning algorithms using Artificial Neural Network (ANN) piled in multilayers. Figure 4 depicts one of the Deep Learning architectures: Deep Boltzmann Machine. The advantage of the algorithm is that we need not extract feature values for pattern recognitions: the algorithm extracts them. The algorithm treats raw data, e.g., pixel data, as input data for input nodes of ANNs in which feature values are extracted and the extracted feature values as output data of the ANNs are used for input data of another ANNs in another layer. ANN structures as the learning model have been devised in resent researches. Deep Boltzmann Machines (DBM), Deep Belief Networks (DBN), and Convolutional Neural Networks (CNN) are popular architectures in the Deep Learning field. A lot more Deep Learning architecture appears in the document written by LISA lab (LISA lab 2015). Deep Learning has powerful possibilities to advance the intelligent agent technologies. The remainder of this section focuses on the state-of-the-art researches about Deep Learning which can be adopted to the intelligent agents as IUI.

In the video game research field, there are several interesting researches which have



Emotion-Based 3D CG Character Behaviors, Fig. 4 A concept of Deep Learning architecture: the RBM in the figure means Restricted Boltzmann Machine

potential to be adopted to intelligent agent behaviors. Mnih et al. introduced a Deep Learning research in which a machine trained by *Reinforcement Learning* method played Atari 2600 games and got high scores than a human expert in several games (Mnih et al. 2013). The authors used raw pixel data as input data for CNN and apply its output data to Q-Leaning, which is a kind of Reinforcement Learning method. Although the research target is not the case of in 3D VR world, the method might be hints for developing intelligent agent behaviors in video games. As a research about 3D video games, the approach of Min et al. provides interesting results to think behavior models for the intelligent agent. The authors introduced a goal recognition framework for *Open World* game (Min et al. 2014). The research used action log data of game player in a first-person viewpoint game as training data set for Stacked Denoising Autoencoders (SdA), a kind of Deep Learning architecture. The action log data are categorized into five parts: *Action Type*, *Action Argument*, *Location*, *Narrative State*, and *Previously Achieved Goals*. The research obtained results of outperforming the previous goal recognition approach based on Markov logic networks. The concept to apply player's action data in VR to machine thinking and decisions will be useful to develop intelligent behaviors of human-like agents.

Away from researches around intelligent agent behaviors, then, we focus on researches around Affective Computing for detecting and recognizing human emotions. Neagoe et al. introduced several Deep Learning model for facial emotion recognition (Neagoe et al. 2013). The research focused on models based on CNN and DBN. The models recognized seven emotion categories, *Happiness*, *Sadness*, *Surprise*, *Anger*, *Disgust*, *Fear*, and *Neutral*, by using facial images in JAFFE database. The emotion recognition results got high scores than the results of other benchmark algorithms: Nearest Neighbor (NN), Support Vector Machine (SVM) with RBF kernel, and SVM with linear kernel. Albornoz et al. introduced an effective method to classify seven emotions, *Anger*, *Boredom*, *Disgust*, *Fear*, *Joy*, *Sadness*, and *Neutral*, from speech utterances data by using RBM and DBN which obtained better scores than a multilayer perceptron classifier (Albornoz et al. 2014). Although Neverova et al. approach which detects gestures by using Deep Learning method is not for emotion detection, the concepts and methods might be applicable to the human emotion detection (Neverova et al. 2014). Martínez et al. investigated the utility of Deep Learning approaches for modeling affects comparing several types of CNNs. The authors tried to find emotional manifestations of *Relaxation*, *Anxiety*, *Excitement*, and *Fun* form skin conductance signals and blood volume pulses while a user play a video game (Martínez et al. 2013). Emotion recognition from Electroencephalogram (EEG) by using Deep Learning method is one of the futuristic approaches. Jirayucharoensak et al. applied

power spectral densities of 32 channel EEG signals to their recognition method based on Stacked Autoencoders which classified nine emotion states: *Happy*, *Pleased*, *Relaxed*, *Excited*, *Calm*, *Distressed*, *Miserable*, *Depressed*, and *Neutral* which are allocated in Valence-Arousal dimensional emotion model (Jirayucharoensak et al. 2014).

These state-of-the-art technologies about agent behaviors, emotion detections, and emotion recognitions will become useful hints to develop intelligent agents with feelings and emotions as IUI as future works.

Conclusion

This article introduced several researches related to intelligent agent works as user interfaces which can understand humans' emotions and can behave against them. Recently, these fields become more hot tops because several breakthrough researches focused on Deep Learning technologies. These results of the researches would be applied to robotics fields. According to the advancement with these researches, an intelligent agent as a user interface communicating with a human would be discussed with many research fields. Because the researches treat several study fields, e.g., *Virtual Reality* and *Artificial Intelligence*, in the future as well as current situations, the researches will evolve with these related fields. These challenging researches will make more friendly relationships between human beings and computers, and enable to build a coexisting society of them.

Synonyms

ACI; Animal-computer interface; DCI; Dog technology; Dogs

Definition

Animal-computer interaction (ACI) and dog-computer interaction (DCI) are extensions of human-computer interaction (HCI), which refer to the usage of technologies for animals and dogs, respectively. However, HCI refers to usage of technologies for humans.

Introduction

Animal-computer interaction (ACI) includes developing a video game prototype for canines. This entry aims to provide context for the problem of attracting dogs to watch screens; the solutions that have been presented, with aims, objectives, and functional/nonfunctional requirements; the perspective that this project makes to the research field of ACI; and the scope of the entire project (Mancini 2016).

ACI is a relatively young but expanding field of research with a lot of progress made in recent years all across the world. However, there are still a number of questions that need answering, such as the following: How do we change the design of human applications to allow animals to interact with them (Mancini et al. 2012; Mancini 2013, 2017)? How can we have animals use technology without human assistance (Hirskyj-Douglas and Read 2014)? What kind of applications benefit animal welfare (Geurtsen et al. 2015; Broom 1996; Rehn and Keeling 2011)? How can we analyze how dogs feel about the applications that we present them with (Baskin et al. 2015; Mankoff et al. 2005).

All of these questions are being asked so that researchers can understand how to properly design various hardware and software for future ACI projects, particularly for dogs. However, although these questions are important in the design of the research, the main question that authors are trying to solve with it is: What can be done to attract dogs to a computer screen in order to use the application created for them?

One of the most essential steps in ACI design is getting the dogs to initiate interaction with the application; however, in order to do that, they need to be interested in interacting with the application in the first place. To achieve this, developers of ACI applications need to establish appropriate techniques that they should be employing in the design of their applications. The problem, however, is that there are no definitive ways of implementing this essential step in ACI design. This leads to extra time and resources being spent by developers trying to understand what exactly they can do in order to solve this problem themselves. A comprehensive review is needed in detail of the various solutions which researchers in the field have produced, to see which ones can be generally applied to each type of application, based on the nature of the hardware and software that are need for the developing stage.

To design and implement any interactive application for animals (Zeagler et al. 2014) in the form of a video game prototype that attracts the attention of dogs and be useable by them (Nielsen 1995; Kjeldskov and Graham 2003), some main steps are required which will be discussed in this entry. This means designing the application using various UML diagrams and techniques; developing a demo via chosen programming language; and having a selection of test participants (all canine) to interact with it, under ethical conditions (Grillaert and Camenzind 2016), in order to ensure that the application meets the specified requirements. The most important aspect usually is to ensure that the video game is fit for purpose. This is the most crucial part of the study, as cannot be solved the main problem of understanding what attracts canines to screens without ensuring that it is certainly a video game with which dogs would be interested in interacting. Otherwise, it would be pointless to have controlled experiments, as they are more than likely to ignore anything that is not designed with them in mind. This research references to what dogs are interested in and looks to incorporate those interests in the video game, in order to come up with the list of interests for dogs in the field of ACI.

Methods

Giving the canine incentive to notice and pay attention to the screen which your application is being displayed on is one of the most essential steps in initiating interaction between dogs and software. This is evident in the experiments that has been researched which all used some technique to attract dogs to their own screens (BBC 2018; Baskin et al. 2015; Geurtsen et al. 2015). The use of techniques like this can also provide additional benefits to familiarize dogs with the hardware that researchers want them to use, such

as the experiment by Dr. Lisa Wallace whose use of screen paste taught dogs how to interact with their own touchscreens using their tongues. Various such techniques will be documented, and their effectiveness will be detailed within this entry, so that researchers can understand why they are important and possibly use them in their own experiments (Burghardt 2005).

Placing Confectionery Items on a Screen

One of the more unique techniques for attracting dogs to a screen that researchers and scientists have been using as of late is to place confectionery items on the screen of the computer/tablet. Dr. Lisa Wallace from the Eötvös Loránd University has been using this technique in order to try and get dogs to interact with their brain training program on a tablet touchscreen. They would first smear a flavored paste all over the touchscreen without turning on the tablet and have the canines lick it off. They would then start the application and smear some more paste on the screen to have the dogs make contact with the application using their tongues. Once the application detected them touching the screen, they would receive a dry treat from a dispenser below the tablet; after some time, paste was no longer required to convince the dogs to lick the touchscreen and interact with the application, as they had now learned how to interact with it as the scientists had intended (BBC 2018).

Sound Design

One of the best senses that dogs possess is their ability to hear, which is generally considered better than that of humans. Their hearing spectrums range from 40 hz to 60 khz (Jensen 2007), and moreover they can locate the source of distinctive sounds (Geurtsen 2014). As stated earlier, we want dogs to exhibit playful behavior and hunting instincts with the prototype, and thanks to this excellent hearing range, certain sounds can be used to help initiate this behavior when it is needed to interact with the video game. The sounds that dogs will react to can vary on a case by case basis: some may prefer the sounds generated by squeaky toys if they particularly enjoy playing with them, or if a dog prefers hunting small animals, then it would probably respond to sounds that they would expect to hear from small animals, e.g., mice rustling through grass (Singer 1995).

A case has been made for this by researchers Golbeck and Neustaedter (2012), who in their project to design a pet monitoring device (for pet owners and canines to call and interact with each other) used a soundboard (among other ideas) to attempt to attract dogs to their prototype system. The soundboard consisted of sounds such as dog barks/howls, cat sounds, squeaky toys, and other sounds that they believed would interest dogs and could be activated remotely by the pet's owner to play the sounds through the monitoring system. In their experiment to have dogs interact with their monitoring system, they would have human users use the soundboard to attract their dogs to a pre-placed laptop screen in order to start interacting with their pet through the monitoring system. All but one of the dogs successfully came to the screen, the lone exception being a golden retriever that was too excited to pay attention to the sounds being played (Golbeck and Neustaedter 2012). One of the best ways to recognize what sounds dogs would want from an application would be the use of dog personas gathered from canine participants (Hirskyj-Douglas et al. 2017).

Laser Pointer and Visual Cues

The same experiment mentioned above also attempted to make use of the dog's visual sense by two different means. The first was a laser pointer, and the second a virtual object in the form of a tadpole, both of which were displayed remotely on the screen.

Discussion

This section contains discussions on the effectiveness of each technique and what have been considered in existing methods to make them engaged as much as possible.

Placing Confectionery Items on a Screen

Placing confectionery items on a screen has proven to be very useful for the particular experiment demonstrated as they managed to show how

useful it was for training dogs to use their devices with their tongues. Eventually they managed to have their dogs use the tablet device without the need for confectionary pastes on the screen, proving that this is indeed a great technique for having dogs engage with a computer screen.

There is only one problem with this technique, which is that it really requires specific equipment in order for anyone to make use of it properly. In the experiment, it was specified that the confectionery items they placed on their tablets was a flavored paste that was completely smothered all over the screen for the dogs to lick off. The problem with this is that most computers are not designed to have any kind of confectionery item, let alone flavored paste, smothered over their displays. There should be a few exceptions such as the devices they used in their experiment. (Note: The devices used in the experiment were not specified in the information source that have been examined (BBC 2018).) However, it would require dog owners to go out of their way to find that equipment if they want to try this technique themselves. Most dog owners would be completely averse to trying this technique, so as not to risk causing any kind of damage to their own computers due to the use of paste on their displays. This particular technique has not been taken into account as there was no access to the necessary technology, but there are rooms to acquiring the means necessary to try it in the future.

Sound Design

The use of specific sounds in DCI seems to be the most viable and generally best method for attracting dogs to a screen. This is for several reasons, the first of which is that dogs very much respond to recognizable sound effects and will tend to locate the source of recognizable sounds as soon as they hear them; therefore it should theoretically lead them to the computer, which they will investigate upon realizing that it is the source of the sound. Again, this has been proven by the experiment by Jennifer Golbeck who had almost all the participants in their experiment attracted to the screen via their own pre-developed soundboard (Golbeck and Neustaedter 2012).

Another reason for this being a viable technique is that it is a very easy method to use for attracting dogs to the screen, since all you really need is a variety of sound files that would attract the attention of canines upon hearing them. Developers of dog-centered applications and dog technology should be able to make use of this technique in some form by implementing sound files within their projects.

The only problem that some people would have with this method is that developers would have to take time to research what kind of sounds dogs would be interested in. This is to ensure that they use as many as possible within their projects, as some dogs may not have the same interest in certain sounds as others. Dog owners would need to experiment themselves and see which sounds from the variety that developers have provided catches the attention of their particular canine.

In the experiments with this technique, the majority of the participants expressed a moderate to great amount of interest toward the computer when sound effects are used in the video game prototype, particularly squeaky toy sounds. Some of their behavior patterns indicated interest toward the source of the sound as they would bark and jump toward the screen recognizing it as the source of the sound. However, the only problem is that during the experiments, one of the canines was confused by the sounds, as they would attempt to stick their nose and paws underneath the stool that the host device was placed on. This indicated that the canine did not recognize the laptop as the source of the sound and instead was looking for a squeaky toy underneath the stool.

Laser Pointers and Visual Cues

Judging by the research, this technique may not be as viable as the other methods described earlier, as proven by the experiment by Jenifer Golbeck et al. In their own experiment, they tried to attract the attention of dogs with both a laser pointer and a tadpole game playing on their computer screen, but with little success of attracting the dogs successfully to the screen (Golbeck and Neustaedter 2012). This is

because these objects were simply not very interesting to the canine participants, as other experiments have managed to successfully attract dogs to screen via screen cues, such as the one done by Sofia Baskin et al. Their experiment used two different kinds of visual cues, both a ball and mouse type object that would move around the screen. It was reported in this entry that both of the canine participants used in this experiment had taken interest in the objects by exhibiting certain behavioral patterns that indicated this (Baskin et al. 2015). That leads me to conclude that the use of visual cues can only work on a case-by-case basis for canines as they are only individually interested in certain objects.

If developers want to use visual cues, then it would be wise to implement a variety of objects in their projects to ensure every dog they work with has something that will interest them. However, depending on what kind of application they are developing, they will either have to develop these cues themselves, which take a lot of time and work, or get them from somewhere else, such as the Unity Asset Store. The latter option can be considered very expensive, depending on what kind of assets the developer needs, how many they need, and whether they are made at the quality level that the developer needs them to be at in order to use them properly.

Conclusion

When comparing all three options for attracting canines to a screen, it is safe to say that the most viable method that developers can utilize is the use of sound cues. This is due to various facts including that any sounds that developers require are easy to access and, in most cases, do not have any drawbacks to downloading them, such as fees; they are very easy to implement in most software applications aimed toward dogs; and they have been proven to be the most successful method when tested with a large range of dogs (Golbeck and Neustaedter 2012).

However, this does not mean that the other two methods are nonviable, as they each have their own useful factors for attracting dogs to a screen. Factors such as teaching fogs on how to use a touchscreen with their tongues, as well as to attract them to the screen, and keeping them engaged with the screen for a prolonged period of time when they notice that something of interest is there have been investigated by Baskin et al. (2015).

Overall, the viability of each method depends largely on the kind of hardware and software that DCI developers are using for their particular project. The viability also depends on the variety of assets used with each method and how well they use them for getting the dogs' attention. If the available options for each method are researched well, chosen well, and implemented to the highest standard expected of them, then they should overall have success in attracting dogs to their computer screen.

Augmented reality displays; Visualization techniques in augmented reality

Definition

Augmented reality is a combination of technology and interaction techniques to superimpose virtual objects onto the real world. Data or information visualization aims to provide visual ways to help users to fastly comprehend and interpret data, mainly when the subject is abstract. As such, there are different approaches to enhance visualization using augmented reality.

Introduction

Augmented reality (AR) can be defined as a variation of virtual reality (VR) in which virtual objects are superimposed onto the real world (Azuma 1997). It can also be understood as one class of displays in the reality-virtuality continuum (Milgram et al. 1995).

Importantly, augmented reality systems share three characteristics: combine virtual and real objects, allow real-time interaction, and perform

3D registration (Azuma 1997). Each of these requirements can be met by different technologies, as well as metaphors, which are explained in this text.

Visualization can be defined as the use of visual representations, sometimes interactive, to enlarge cognition and, thus, help users to comprehend and interpret abstract data (Gershon and Eick 1997; Card et al. 1999; Liu et al. 2014). Visualization enhanced by AR uses techniques of AR to enlarge cognition in three-dimensional interactive environments joining virtual and real objects.

Examples of Enhanced Visualization by Augmented Reality

This section presents a few examples of existing and potential systems in which information visualization is enhanced by augmented reality. Those examples are useful to give context to the technologies and techniques discussed later.

Visualization of Invisible Phenomena

Augmented reality can be used to provide visual information about phenomena, such as electromagnetic fields, which are not visible to the human eye. Similarly, it can display consolidated information that might be distributed or occluded; the system proposed by Bhattarai et al. (2020) aims at improving situational awareness of firefighters in a fire environment.

Enhancing the Study of Art Works and Cultural Heritage

Augmented reality systems might be used to visualize additional information over paintings, such as layers of pigment, construction lines, as well as highlighting separate subjects. A number of mobile augmented reality systems have also been developed to enhance the visitation of cultural heritage sites by presenting layers of additional information and virtual reconstructed buildings and other objects (Vlahakis et al. 2001) (Choudary et al. 2009).

Facilitating the Process of Architectural and Interior Design

Applications of augmented reality have been developed to provide visualization of furniture for design and decoration (Viyanon et al. 2017) (Nasir et al. 2018). The main motivation is to provide a cost-effective solution to experiment with different options and configurations of furniture. For this purpose, marker-based and markerless solutions are deployed, so that 3D models of furniture in actual scale can be visualized in a room and thus, space constraints, as well as aesthetic concerns, can be evaluated.

Improving the User Experience in Retail Applications

There are augmented reality systems that improve user experience by showing additional layers of information that are relevant to the users. Two examples are: displaying nutritional information on images of actual food (Jiang et al. 2018), and allowing the user to try virtual shoes, visualizing pressure points on the feet (Bizen et al. 2021).

Augmented Reality Display Technologies

Augmented reality (AR) is a concept instead of a specific technology. Therefore it is possible to implement such a concept using different solutions. Following, it is presented the most common technologies used in AR for displaying spatially registered visual information onto the real world.

Handheld/Mobile

Mobile applications are the most popular way of enhancing visualization via AR. Almost all current smartphones and tablets incorporate all technologies necessary for capturing real-world scenes, tracking movements, and superimposing registered visual information over the real world. Only a software layer is required to produce the AR effect. The most commonly used metaphors are “window” and “mirror.”

Desktop/Large Screens

Before mobile technology has incorporated high-quality video processing and tracking technologies, the most common way of producing AR was via desktop displays or large screen projections (via datashow). The "mirror" metaphor was most used in this case, as the user watched his/her actions by looking at the display screen and not directly to where the action was taking place in the real world. In the beginning of AR popularization, the most common way of registering was based on cheap fiducial markers (see the section on tracking technologies).

Head-Mounted Display (HMD)

Goggles, technically known as HMDs (head-mounted displays) in VR and AR applications, are mostly used in professional or public installations, due to high costs and complexity involved in setting up and use. It is expected that in the future those goggles would be as cheap and easy to use as sunglasses, which would eventually surpass smartphones and tablets as the preferred mobile solution for AR. There are two main approaches for producing AR effect via goggles: optical see-through and video see-through.

Optical See-Through

In this approach, a semitransparent screen is used, allowing the direct visualization of the real world while showing registered superimposed virtual images, digitally produced on that screen.

Video See-Through

It is basically a VR HMD, combined with a video camera that captures the real-world scene, which is augmented with registered superimposed digital synthetic elements. What the viewer sees is totally digital, but the sensation is of watching directly to the real environment with AR effects.

Projector-Based (Spatial AR)

This solution avoids the use of HMD by projecting virtual images directly over physical objects, altering their perceived texture or even producing the illusion of movement.

Visualization Metaphors

Metaphor can be understood as a main principle of mapping an application domain to a visual universe (Averbukh 2001). In the design of human-computer interfaces, metaphors are used to provide a conceptual reference that might aid users in understanding abstract data. Thus, some behaviors and properties of the reference entity are represented or instantiated on the interface (Preece et al. 2015).

It is interesting to note that visualization metaphors are found most often in AR systems, in which the mediation of the display technology cannot be hidden from the user, such as handheld/mobile, desktop/large displays, and projector-based AR.

Mirror

The mirror metaphor is found in desktop/large screens and handheld/mobile AR applications in which one or more cameras are pointed at the user and a mirrored image, composited with virtual objects is displayed. It leverages the familiarity of interacting with and inspected one's reflected image in the plane of the mirror to promote the visualization of the virtual objects.

Window

The window, or sometimes lens, metaphor is also encountered in handheld/mobile and desktop AR applications. In this case, the display surface is used as a framed viewport to the enhanced visualization. As such, it is expected that the virtual objects can only be seen through the limited display area.

X-Ray Vision

The X-ray vision metaphor can be found in projective AR systems. The image with enhanced virtual elements is understood as a view of the inside of the objects onto which it is projected.

Customized Metaphors

In this type of metaphor, developers seek to include visual objects (e.g., images, icons, 3D

surfaces) in their systems to represent abstract data in order to help users to comprehend the dataset that is being visualized in an AR system.

Tracking Technologies

In AR systems, tracking refers to the process of identifying reference objects or locations in order to perform 3D registration of the virtual objects: the correct geometric alignment of those objects onto the real world. There are a number of approaches for tracking, which may be grouped into four categories: magnetic, vision-based, inertial, and GPS-based (Billinghurst et al. 2015).

Magnetic Tracking

Magnetic tracking involves a transmitter and one or more receivers of magnetic fields; the variations of that field's properties allow for the determination of each receiver's position and orientation in space. While magnetic tracking allows for fast and accurate tracking, it is also limited to small volumes in space, and it is sensitive to electromagnetic interference in the environment.

Vision-Based Tracking

Vision-based tracking involves the detection of features in an image captured by a camera, which can work with visible or infrared light. The features may have been added artificially, in the form of fiducial markers; they may also be naturally occurring in the real world, such as patterns of lines, shapes, or textures, which are detected by image processing algorithms. A fiducial marker is a piece of any material containing a nonsymmetric pattern used to define the place where a virtual object should be included in a real scene. The cheapest way of producing these markers is by printing an image in common paper. Fiducial tracking is comparatively simpler, but the requirement for markers added to the environment limits its applicability. Natural feature tracking is more flexible, but the related algorithms require more processing power. In both cases, vision-based tracking is influenced by factors such as lighting conditions, occlusion and the presence of unexpected objects in the scene, which can disturb the pattern recognition process.

Inertial Tracking

Inertial tracking makes use of inertial sensors such as gyroscopes and accelerometers attached to a tracked object, to determine its position and orientation. Those sensors are not susceptible to electromagnetic interference, but they are affected by drifting, which reduces their accuracy.

GPS-Based Tracking

The use of GPS tracking for augmented reality systems is feasible in outdoor environments, to determine the user's position relative to a large area. Due to precision limitations, it is often combined with other forms of tracking.

Everyday Virtual Reality

Tom Alexander Garner, Wendy Powell and Vaughan Powell
VIA Research, University of Portsmouth, Portsmouth, UK

Synonyms

Immersive technologies; Mixed reality; Virtual reality; Virtual systems

Definition

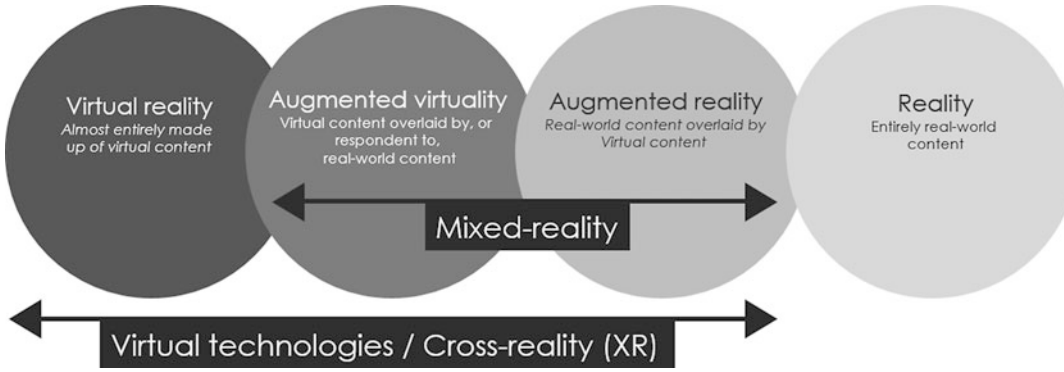
Everyday virtual reality (VR) can describe any activity that the majority of us would typically engage in at least once per day, experienced through the medium of VR. Its meaning is interwoven with user experience and the concept of technological acceptance, which describes users' feelings toward a technology's design and its intended purpose. In some contexts, VR already functions as an accepted and almost ubiquitous part of everyday life, while in others, it remains a novel technology – but one with great potential for ubiquity in the near future.

Introduction

First coined in 1987 by Jaron Lanier (see Slater and Sanchez-Vives 2016), the underlying meaning of VR is one that has broad similarities but also slight differences between its various definitions. VR definitions broadly fall into one of two categories, one more technology focused and the other more centered upon user experience. The technological definition describes VR as multidimensional, computer-generated content that is perceived by a user as a continuous and distinct environment (Craig et al. 2009; Seidel and Chatelier 2013). The user experience definition by comparison explains VR in terms of "presence" (feeling physically/cognitively that you are *in* an environment). Steuer (1992), for instance, argues that to be considered VR, a system should evoke a degree of presence in the virtual world that is approaching our sensation of presence within the physical world. In further delineations, VR using head-mounted displays (HMDs) is normally termed "fully immersive VR," with "semi-immersive VR" referring to the use of flat screen displays. Additionally, there is the issue of the reality-virtuality continuum (Milgram and Kishino 1994) which encompasses VR, augmented reality (AR), and augmented virtuality (AV) – all broadly outlined in Fig. 1.

By popular definition, VR is again defined technologically, but in more restrictive terms. Here, VR describes a system using a consumer-grade HMD with head and/or body tracking. This article will focus primarily upon VR by the popular definition, looking at the use of contemporary PC and mobile VR devices in everyday purposes. The rationale for this focus is that, as the term would suggest, popular VR encompasses the technology most available to the general public, with its development largely dictated by user experience requirements in everyday use contexts.

Everyday VR emerged as a more formal concept in 2015, with the first IEEE Workshop in



Everyday Virtual Reality, Fig. 1 Edited version of Milgram and Kishino's "reality-virtuality continuum"

Everyday Virtual Reality (Simeone et al. 2015a). Here the concept is described as the use of consumer-grade VR technology in an everyday setting, such as a domestic or office environment.

Current Everyday VR Technology

Broadly speaking, consumer-grade VR technology can be separated into four main classes based on their platform; PC-based (also known as "tethered VR" – *Oculus Rift*, *HTC VIVE*), smartphone-based (*Samsung Gear VR*, *Google Cardboard*), console-based (*PlayStation PSVR*), and most recently, standalone mobile platforms (*Oculus Go*, *Lenovo Mirage*). Each class of VR comes with a unique set of advantages and disadvantages, with each proving more capable in certain contexts while less capable in others. Table 1 below summarizes these pros and cons across each platform class.

Speaking again in more general terms, tethered and smartphone systems are largely presented to consumers as antitheses of one another, with the majority of one platform's advantages mirroring the other's disadvantages. Console systems are positioned somewhere in between on most points of evaluation while the newer standalone systems are more comparable to smartphone VR, but largely differentiate themselves with improved optimization – being built bespoke for VR. Throughout this article, we shall refer back to these pros and cons to show how diversity in VR technology is supportive of its everyday use.

Everyday VR in the Home

Recreational use is undeniably the primary way in which everyday VR has infiltrated our homes. Though the function of VR in the home began with video games, the technology has quickly been developed to support our interactions with various additional forms of media. All four VR platforms support streaming of television and film, with all but console VR supporting web browsing – enabling users to interact with web-based content within an immersive VR environment.

Central to the evaluation of technology used for accessing media is the concept of user experience (UX). As Albert and Tullis (2008) observe, the defining requirements of positive UX are that the user feels involved, interested, and in control. Similarly, research concerning UX for web browsing indicates that the interface should essentially strive for perceptual invisibility, becoming an extension of the user to enable the most efficient and direct interaction with internet content (Yu and Kong 2016). This presents a significant challenge to VR which, as a novel consumer technology with different means of interaction (e.g., gaze selection in place of touch screen and mouse interfaces) is anything but invisible. As a result, VR faces a significant challenge in becoming a

Everyday Virtual Reality, Table 1 Summary of key advantages and disadvantages of VR, separated by platform

	VR platform			
	PC/Tethered	Smartphone	Console	Standalone mobile
Advantages	Visual fidelity Greater comfort (supports extended use) Integrated headphones 6 degrees of freedom (positional tracking) Motion controllers as standard Greater field of view (110°) Room-scale VR Highly adjustable HMD (straps, lenses)	Very low-cost headsets Uses hardware many of us already have Highly portable Easy to setup and operate Wireless reduces trip hazards More social More reliable Poor optimization (heat issues/battery intensive)	Very comfortable for extended use Integrated headphones Average FOV (100°) 6 DOF (positional tracking) Motion controllers as standard Easy setup and use More reliable	Better mobile optimization Highly portable More reliable More social Greater comfort Wireless reduces trip hazards Easy setup/use 6 DOF (limited) Controllers as standard Integrated headphones FOV (100°)
Disadvantages	High cost Requires powerful PC Requires large space Lacking portability Increased risk of trips and falls with wires More difficult to setup More liable to technical problems More isolated experience	Poorer visual quality More susceptible to frame lag, causing motion sickness Lacks positional tracking Controllers not standard Less comfortable for extended use Poorer FOV (90°)	Limited application (usage restricted to video games and media) High cost of both console and VR headset Lacking portability Lacking room-scale VR	Poorer visual quality More susceptible to frame lag, causing motion sickness More expensive than smartphone Room-scale VR is limited Less adjustable HMD

genuine alternative to PC and touchscreen smartphones interfaces; both of which have been heavily refined in terms of both usability and UX for many years (Lobo et al. 2011). Ongoing development in smartphone and computer interfaces also means that VR will likely be playing a perpetual game of catch-up.

Of the four VR platforms, smartphone systems arguably standout as the most appropriate for this particular everyday context; its accessibility, ease of use, and wireless operation all support the above UX requirements, while many of its limitations (poorer graphics, lacking positional tracking) are less applicable in this context. That said, issues such as extensive power consumption and heat generation limit users to significantly shorter sessions when compared to using a non-VR smartphone interface. Additional barriers to its technological acceptance include social issues, relating to feelings of social awkwardness in "wearing a computer" in public (Busel 2017).

More in the domain of academic research, "substitutional reality," features as a particularly interesting area of development. Simeone et al. (2015b) define substitutional reality as "a VR experience that incorporates physical objects into

the virtual world by using them to represent objects relevant to the virtual context" (p. 3307). The general idea is that real-world objects are tracked in virtual space and mapped to virtual objects that may be very different in nature, but comparable in their weight and dimensions. In this instance, a bottle may become a vial of magic potion, a broom a lightsabre, an umbrella may even become Mjolnir (Thor's Hammer). While not yet commonplace in our homes, substitutional reality is arguably an advocate for the "everydayness" of VR, as it utilizes a range of distinctly everyday objects about the home and repurposes them to create multisensory and deeply immersive mixed-realities.

Although VR is highly unlikely to replace traditional interfaces for 2D media content, it is in the third dimension where the technology has the most potential. 360° films and television programs can be viewed upon 2D screens but lack the immersive quality of head-tracked HMDs, to the extent that such content is essentially exclusive to VR. As the majority of web content is two-dimensional, however, there remain significant limitations to the perceived usefulness of VR for web browsing. That said, research is pursuing this issue by exploring various means of deploying immersive, 3D websites built upon existing web-standard technologies (de Paiva Guimarães et al. 2018). The future success of VR in this context remains an optimistic but unknown quantity.

In the Classroom

Virtual technologies are becoming increasingly notable within education and skills training. A recent meta-review by Gutierrez-Maldonado et al. (2017) noted that $1.2 billion has been invested globally in the last couple of years to increase access to virtual content, specifically by supporting the development of HMDs. This is not at all surprising as some of the fundamental characteristics of VR, namely the potential to create accurate and immersive simulations of real-world phenomena, are ideally suited to contextualizing and grounding complex and abstract information. A further review by Jensen and Konradsen (2017) observes that VR offers support to memory and spatial awareness training and can also help with the development of motor skills and emotion control. One of the most significant benefits of VR in classrooms relates to the concept of the "extended classroom" (see Loureiro and Bettencourt 2011), with the technology enabling students to engage with simulations of various locations and events that would be expensive, impractical, or even physically impossible to experience otherwise.

VR within an educational context has built upon the progress made by semi-immersive virtual systems; serious games that present the user with a three-dimensional world from a first-person perspective. A prominent example of this would be in the use of *Minecraft* (Persson et al. 2011) in schools. As Nebel et al. (2016) point out, games such as this are deeply supportive of constructivist pedagogy (contextualized learning through active construction of knowledge) and encourage cooperative learning, self-management and provide an accessible route to understanding complex systems. Minecraft is currently being used in numerous school systems all over the world to teach an impressively broad range of academic subjects (Short 2012). VR arguably provides key additional benefits beyond those offered by traditional serious games. These include greater perceived realism through more immersive audiovisual content and more naturalistic controls, and a deeper connection to the content through enhanced feelings of presence (see Freina and Ott 2015).

Although its advantages are distinct, the likelihood of seeing VR as a ubiquitous technology within this everyday context is dependent upon its disadvantages being overcome. Jensen and Konradsen (2017) note that the benefits of VR over traditional computer interfaces are largely limited to those stated above and that the technology also presents issues that can be counterproductive to learning, such as the prevalence of cybersickness and the potential of the immersive experience being a distractor from the learning task. One of the primary current issues with classroom VR is financial feasibility. Though

a far more significant issue 15 years ago (see Mantovani et al. 2003), the costs of purchasing, maintaining and supervising the operation of HMDs in the classroom remains prohibitive for many schools (Merchant et al. 2014). The investment mentioned above, however, seeks to overcome this issue by driving down the consumer costs of the hardware, making it more compatible with cheaper computers and developing the potential of smartphone-based VR (Gutierrez-Maldonado et al. 2017).

At the cutting edge, research into classroom VR is largely prioritizing developments in multiuser cooperative systems (Greenwald et al. 2017), integration of bio/neurofeedback (Blume et al. 2017), and designing for students with special educational needs such as autism and attention-deficit hyperactivity disorder (Neguț et al. 2017). In our current classrooms, fully immersive VR may not be as "everyday" for most students as semi-immersive systems, but in some schools, it is being used with intent and as an integrated part of the curriculum.

In terms of technological acceptance in this context, classroom VR studies have revealed perceived usefulness and openness to new learning methods to be significant factors (Liou et al. 2017). Prior experience of technology has also been shown to influence acceptance (Neguț et al. 2016), suggesting that the use of VR in the classroom will continue to expand, in part due to the simple fact that we as humans are increasingly growing up with the technology.

In the Workplace

The extent of VR's everydayness within workplace environments varies significantly between specific industries, but overall this particular context is where VR has become the most normalized and the technology is at its most "mature, stable [and] usable" state (Berg and Vance 2017: p.1). The entertainment market for VR has endured a volatile few decades. In contrast, VR developments in industry continued unabated, as the motivations for progress were not tied up in the consumer hype and inflated expectations that plagued the entertainment market. The result of this is that VR has been steadily improving and integrating itself as an everyday technology within industry for decades. At present, some of the most prominent applications of VR in the workplace are telecommunications, data visualization, and rapid prototyping.

Telecommunications is arguably an application of VR that could have also featured in the above discussion on VR in the home. The grand ambition of telecommunications systems is to evoke a sense of telepresence that is equal to face-to-face conversation. Coined by Minsky in 1980, telepresence originally described a feeling of "being there," experienced by individuals remotely operating robots. In a more recent definition by Ting et al. (2017), telepresence refers to "the degree of awareness of another person in an interaction and the consequent appreciation of an interpersonal relationship" (p. 382). The use of technology as a medium for communicating across great physical distances is by no means a new concept, with teleconferencing and videoconferencing systems possessing an extensive history of development and a now global usage. VR aims to bring telecommunications closer to realizing its grand ambition, with recent research projects exploring the use of VR combined with facial and body capture technology (Thies et al. 2016) and "mixed-reality telecoms," in which webcam feeds of multiple speakers are presented within a single, multiuser virtual environment (Regenbrecht et al. 2015). The potential value of VR communications is substantial across every sector of industry, enabling users to conduct presentations, seminars, board meetings, job interviews, and more, all with a quality of communication that is closer to in-person contact, but across global distances.

Early data visualizations began to appear in the early nineteenth century with bar charts, scatter plots, and line graphs (Rimland et al. 2013). Traditional (and much of contemporary) data visualization is graphics-only, two-dimensional, and static, which significantly limits our ability to comprehend complex or evolving information.

In such instances, VR has a powerful potential to overcome such limitations by way of representations that are dynamic, multidimensional, and immersive (Laha and Bowman 2012; Reda et al. 2013). As one would expect, the specific industries heavily utilizing VR for data visualization are those that deal in high volumes of complex data. These include the finance, energy, and pharmaceutical sectors (Marr 2017).

VR's ability to digitally represent architectural designs in actual scale makes it ideally suited to cost-effective prototyping, with users able to experience designs in a way that is far closer the intended final construction than a 2D image or scale model (Wolf et al. 2017). Near-future ambitions for architectural visualization largely concern three main areas: wireless connectivity, multiuser systems, and the integration of Building Information Modelling (BIM). Together, multiuser functionality and the integration of BIM data within VR enables multiple stakeholders (from architects and interior designers, to engineers and construction workers, not to mention the clients themselves) to work much more closely and collaboratively. Here, a single shared environment can present multiple facets of the design, from the aesthetics to the mathematical characteristics of the structure, all of which can be experienced within a single VR representation by everyone, all together and in real time.

Architecture is most certainly not the sole industry currently utilizing VR as a means of rapid prototyping. The ability to evaluate a product concept as a multimodal, immersive, and interactive virtual prototype has benefit to a wide range of industries including the military, aerospace, automotive, and agriculture. In many instances, the value of VR prototyping extends beyond a representation of the product, to a simulation of the real-world environment in which that product would function. This enables product development to improve various aspects of a design, from ergonomics and usability, to construction method and aesthetics (Craig et al. 2009). For those working in such sectors of industry, VR's rapidly increasing usage is making it a prominent element of their everyday working lives.

Out in the World

Everyday VR is not confined to interior applications within homes, schools, and workplaces. Rather its meaning stretches out to exterior venues and even the great outdoors. In recent years, the theatre has taken a significant interest in the potential of VR technology to both enhance and explore new approaches to dramatic performance. As Moneta (2017) points out, associations between theater and VR go back at least 20 years, where the concepts of blending physical and virtual content were initially experimented with. Moneta also points to the use of VR as a means of reimagining existing works, both to allow the initiated to experience a performance in a distinctly different way, and to make such works more accessible to newcomers. One cutting-edge example of VR-theater is *Fatherland VR* (Council 2018), a VR play in which the audience directly interact with multiple virtual characters, some manipulated by a live actor (through motion capture) with others controlled by the computer. On occasions, the way in which a single virtual character is controlled switches between human and computer control, with the audience left unaware.

Since 2015, The British Museum has been incorporating VR into their exhibitions as a means of enhancing the experience and improving educational potential (Rae and Edwards 2016). Here, smartphone VR is preferable largely due to its efficiency of use, specifically the speed at which the headset can be fitted and removed – enabling a greater number of visitors to experience the VR content throughout the day. Recent research has pointed to increased entertainment value as a significant factor in the appeal of virtual technology in museums but also points to the requirement of improved aesthetics and better social presence for VR to acquire greater technological acceptance in this context (Jung et al. 2016). As with other applications such as architectural visualization, museum VR reveals a need for further developments in multiuser systems that immerse users within virtual worlds that can be shared with others.

VR also takes things outside, presenting (for example) visitors of heritage sites the opportunity to experience "smart tourism" (see Chung et al. 2015). Here, VR software that can be downloaded directly to phones and mobile devices provides visitors with access to additional virtual information relevant to the immediate physical environment. Mobile technology, GPS navigation, and object recognition supports location-based content generation and enables visitors to hold their device towards an historic ruin and observe a digital recreation of how it once looked many centuries ago. While research and development in these technologies is ongoing, many applications of these types are already available to consumers across the world.

Lastly, healthcare is one of the most significant applications of VR technology and represents a workplace environment in which professionals are increasingly seeing VR become an everyday presence. Outside of this context, however, everyday VR also extends to healthcare for the wider population by way of its application for exercise. Here, a range of approaches are now available to consumers. These include using VR video-streaming services as a distraction during endurance cardio training and using VR action games whilst wearing body weights to enable inherently engaging activities such as playing games to also provide moderately intense workouts (Holly 2017). As individuals get older, the likelihood that they will engage with VR exercise in an everyday context becomes significantly greater. The technology is now featuring in physical rehabilitation for issues with balance, gait training, mobility, and muscular degeneration, to name a few (see Park et al. 2014; Park et al. 2015; McEwen et al. 2014).

Healthcare, in particular, reveals the benefits of there being a range of VR platforms, each with different pros and cons. For example, smartphone VR is ideal for delivering reminiscence therapy (reminiscing on past experiences as a means of preventing memory loss) as it typically involves 360° video, requiring minimal processing power, but does require greater ease of use and accessibility for both its elderly users and the practitioners delivering the therapy (Benoit et al. 2015). By comparison, physical rehabilitation favors tethered systems as it typically requires full-body tracking with 6 degrees of freedom to enable the system to evaluate the user's movements correctly. Reviews of technological acceptance are generally positive in this context, though studies have revealed that (in line with various findings in other contexts discussed earlier) improvement in ease of use and social presence (i.e., multi-user) are key to raising acceptance further (Roberts et al. 2018).

Closing Comments

To summarize, VR already presents us with new means of engaging with numerous everyday activities, from browsing the web or using film-streaming services, to family days out to museums or to the theatre. The annual workshop on Everyday Virtual Reality is now in its fourth year (Simeone et al. 2018) and is continuing to grow. Several challenges remain however. Motion sickness remains a persistent issue for many users and contemporary headsets continue to cause neck soreness and eye strain after prolonged use. The hardware is not discrete and, in social contexts, potential users remain uncomfortable with the idea of using VR technology in public. Costs remain prohibitive in many everyday contexts and in terms of usability and user experience, VR interfaces continue to lag behind more established technologies. Despite these issues, VR is already enhancing many everyday tasks and procedures that have themselves been commonplace for many decades, and in some cases, even centuries. Ultimately, it is very difficult to make predictions for the future, particularly when considering that VR technology is becoming increasingly interconnected to mixed reality, a concept arguably more compatible with everyday activities. Where VR prioritizes isolated experiences and immersion in virtual worlds, mixed reality favors the integration of virtual

worlds with our shared physical world. For everyday VR, the future is *mixed*.

Experiential media; Interactive displays; Mixed reality; Personalized content; Reactive visuals; Real-time generated content

Definitions

Experiential media (EM) refers to models of media computing that incorporate contextual understanding of human activity, at different scales of time and space, to affect the human experience of the content through such activity. It allows user engagement by utilizing live sensors as input to a media computing unit that then outputs multimedia to output sources, such as displays or speakers. Experiential media is dynamic real-time generated media based on the live physical activity perceived with the goal of achieving enhanced and unified physical-digital experiences (Sundaram and Rikakis 2008).

Introduction

Experiential media (or EM) was used primarily by the museum industry for specialized exhibits using methods of experiential learning (Huang and Lin 2013), but has grown since then into a general tool for experiential content delivery in applications such as digital signage, architecture, hospitality, entertainment, and more. EM is often used for branding and marketing purposes among many other uses. It is growing in popularity as it allows for interactivity and higher user engagement with brands, prolonging the duration of interaction with advertising and increasing

impression counts. With the progression of intelligent computing, using methods such as Artificial Intelligence (AI), greater contextually appropriate EM is possible.

EM utilizes live sensor inputs from devices such as wearables, microphones, proximity sensors, or cameras. This entry will primarily focus on camera-based EM, using machine vision and further narrow down to focus on single camera setups. EM goes beyond classic human computer interface (Sutcliffe 1995) (HCI) as it is touchless, responsive from a distance, and its use of AI technology. It is the natural evolution of traditional audiovisual content as it gradually becomes more sophisticated and starts to become personalized to the viewer/user. EM is defined as "experiential" as it integrates user action in the design, requiring the user to physically act and move in order to experience the full media.

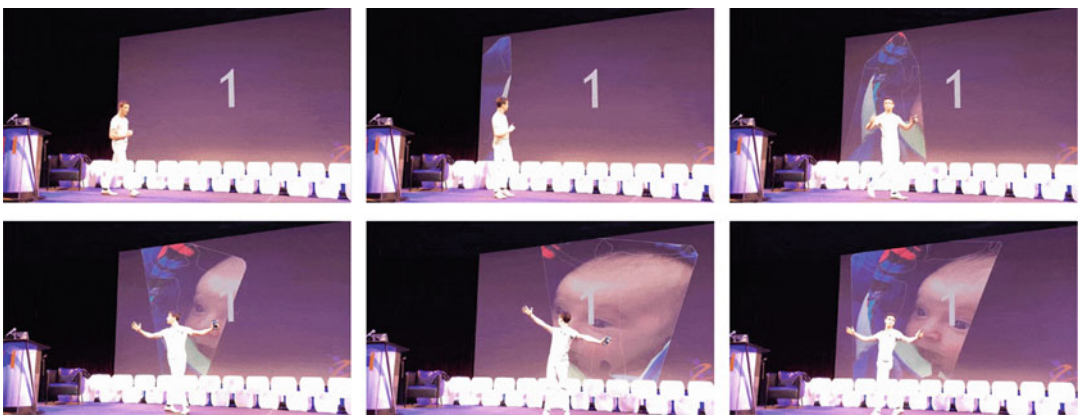
EM has the tendency to shift the user from passive viewer role to an active participant role as its elements will remain hidden or remain at their default behavior unless the user is actively moving in the intended way, as can be seen in Fig. 1. EM differs from mixed reality (Kasapakis et al. 2018) (MR) as it does not necessarily incorporate real world objects but can act as its own autonomous object. EM is presented through display mediums that are built into the environment in ways that are intended to augment or mix with the visual experience coming from physical spaces.

Uses and Frameworks of EM

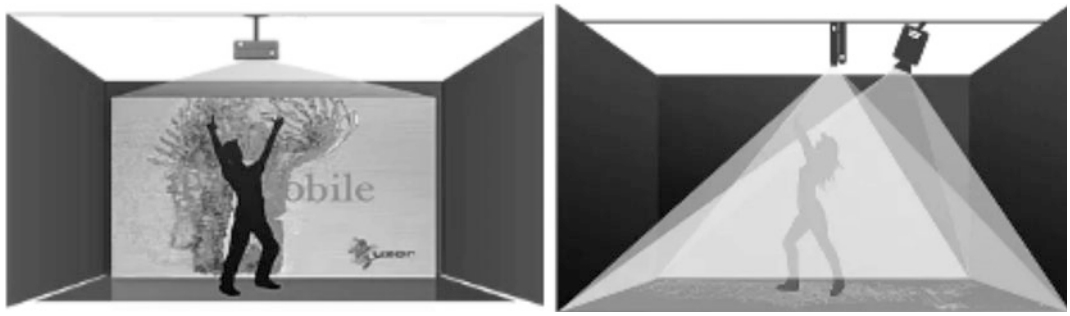
EM has multiple uses, depending on the type of content it displays, such as entertainment, educational, infotainment, wayfinding, advertising, or others. Furthermore, as large format displays become more affordable and prolific, the Digital Signage and ProAudioVisual industry are beginning to offer EM as a tool that combines content generation with immersive experiences. As of now, EM is known to be used in the following industries: hospitality, nightlife, entertainment, gaming, events, public speaking, retail, museums, and experiential marketing.

At the time of writing, the mainstream approaches to creating EM are using platforms and libraries such as Openframeworks, Unity, LumoPlay, and Zuzor. The different platforms are targeted at creators with different levels of expertise: from full coding for developers, such as Openframeworks, to creative suites that allow for rapid customization for graphic designers, such as Zuzor. There are more tools available such as Touchdesigner, Quartz Composer, etc., which are beyond the scope of this entry. A brief description of the mainstream approaches is provided below.

Openframeworks: openFrameworks is an open-source toolkit designed for creative coding written in C++ and built on top of OpenGL (openFrameworks 2020.)



Experiential Media: Using Machine Vision and Sensor-Input to Create Dynamic Real-Time Generated Media, Fig. 1 Experiential Media projected on a wall



Experiential Media: Using Machine Vision and Sensor-Input to Create Dynamic Real-Time Generated Media, Fig. 2 Upright setup (left) and top-down setup (right)

Unity: Unity is a cross-platform game engine developed by Unity Technologies that is popular for Games and Cinematics around 3D content (Unity 2020.)

LumoPlay: Lumo Play is a software solution for Windows to create games for kids using motion, gesture, and touch experiences (LUMOplay 2020.)

Zuzor: Zuzor is an Experiential-Media platform that enables the graphic design industry to easily create experiential media and the Pro-AudioVisual industry to easily deploy experiential media while tracking engagement using AI analytics (Zuzor 2020.)

Real-Time Sensing

As EM establishes a feedback loop between the audiovisual content and the user, a real-time solution to capturing the movement and context of the user is necessary. Machine vision broadly encompasses all industrial and nonindustrial applications that utilize photo detective sensors to perceive an image and utilize software to extract information from the image (Beyerer et al. 2016). The information extracted from the image is then utilized in the system's overall function. When utilizing machine vision for EM, there is a further distinction between real-time and offline usage to sense movement in a space.

EM is used in live performances, where the display medium is on stage responding to dancers or performers on stage (Performances Using Experiential Backdrops – YouTube 2020). Real time capabilities bring EM technology to entertainment with a more robust stage performance (Dubnov 2014). Previously, in many entertainment and staged environments, it was common to utilize offline approaches to create the illusion of audiovisual content as EM. While these approaches may incorporate dynamic generated media, it lacks the key real-time element that is core to this entry. The general approach was often for performers to train to move in synchrony, both temporarily and spatially, with elements of the content to make it appear as though it is interactive and contextual to their movement. This approach is prone to human error as it requires the performers to move exactly the same each time, in the exact same timing and the exact same spatial position, to create the effect of EM for the broader viewers. This approach further limits the participants to individuals that are a part of the production, as they often require numerous rehearsals, and limits an untrained individual from being able to seemingly "interact" with the system.

Machine Vision in EM

The usage of Machine Vision in EM is optimized to be perceived as instantaneous, or close to real-time, with the movement it detects. From an implementation perspective, this often incorporates software optimized to run on Graphic Processing Units (GPUs) in order to reach peak Frames Per Second (FPS). FPS is the rate at which the visual content is updated, for example, 5 fps indicates that the system updates the visual

content every 200 milliseconds. From a psychovisual perspective, a human requires visual content with a minimum of 15 FPS (Li 2009), translating to an update every 66 milliseconds, to perceive the content as continuous and smooth.

Machine vision techniques can be applied with different hardware in different scenarios to offer a range of interactions with dynamic media. Further perspective considerations are required as parts of a user's body may become obscured or no longer directly visible to the camera. From a broader framing consideration, the angle from which the camera perceives the user and the angle from which the user views the display medium need to be accounted for. Other considerations include broader viewers not interacting with the system and their perspective to the user and the display medium showing the dynamic content.

Other than the media-generation procedures that are known to use GPU, machine vision approaches are becoming increasingly optimized for GPUs. Some of the common approaches include:

Gesture tracking and recognition: tracking markers to recognize specific movements (Dubnov and Wang 2015; Wang and Dubnov, 2015)

Bodypix: a deep learning based method to extract a body contour from an rgb image (Wang and Dubnov 2015)

Human Pose Estimation: a deep learning based method to extract body joins from an rgb image (Su et al. 2020).

Setup and Hardware Options

EM constitutes multiple pieces: the sensing hardware, the display medium, and the spatial area the user is detected in. EM falls into two main setup variations as can be seen in Fig. 2, upright (left) and top-down (right). (Eye Setup 2020.) Upright configurations position the camera upright, parallel to the floor. Top-down configurations position the camera facing perpendicular to the floor, similar to a birds-eye-view looking down. The position and orientation of the camera is independent from the positioning of the display. As such, it is possible to create EM using upright activations that project on a wall directly in front of the user or activate a video wall in a different location entirely. Similarly, it is possible to create EM top-down activations that project on the floor as users move through the space or activate the ceiling or a tabletop surface.

For different setup variations, different camera types may be more appropriate. By large there are three main camera types that can be used for different variants of interactions. They are as follows:

- *IR cameras:* utilized with infrared (IR) markers that the user wears on whatever body points or objects would like to be tracked, providing the EM system with a set of (x,y) coordinates (Nawrat et al. 2013).
- *Depth cameras:* typically utilizing projected infrared mapped with structured light or stereo cameras that gives a full RGB-D (red green blue – depth) of the space, providing the EM system a full pixel map (Smisek et al. 2013).
- *RGB cameras:* the standard camera used in most laptops, security cameras, and phones, providing the EM system an rgb pixel map.

The RGB cameras are better suited if the scene is only meant to react to human movement. If the scene is meant to react to broader movement, such as moving objects or those that require a sharp contour, then the depth camera is appropriate and can be used with depth-thresholding. If the screen is only meant to react to the movement of specific objects in the space then an IR camera may be most appropriate. If the EM is designed to only react to human movement then an RGB camera with subsequent artificial intelligence (AI) methods, such as human pose estimation that can be abstracted into contours or a set of body joint coordinates (Sigal 2014), may be enough. With the top-down setup scenarios, a depth camera may be most appropriate as AI models are often not trained on birds-eye-view of humans.

Some hardware solutions may support the different variants simultaneously. One of the early

breakthroughs introducing creative coding and EM to the larger population came with the Microsoft Kinect that was released with the Xbox in 2010 (Smisek et al. 2013). At the time of this writing, a prominent provider for depth cameras, for EM and broader machine vision tasks, is Intel's RealSense (Intel® RealSense 2020) series that offers the most high resolution and physically compact solution in the market that can support any of the three variants described. The other large non-US player is Orbbec Astra that offers a depth-camera solution over usb-2 (Orbbec 2020). Of course more providers exist, but they are outside the scope of this entry.

Analytics

As EM often utilizes a camera to capture RGB, broad demographic analytics can be aggregated about the users. The measures can further be tallied against the specific experiential media displayed at the time that the metric was recorded. EM can have triggers inside the media, where a specific movement by a user can trigger the transition to a different media. As such, the use of a sequence of triggers by users can be recorded to quantify an overall map of the media a user has experienced and the overall trend on trigger activations in scenarios where multiple triggers are present.

Discussion

When designing EM, the effectiveness and impact of the interaction depends on the content design and is affected by context, such as location, the users demographics, and more. Broadly speaking, the memorability of the EM compared to traditional media is enhanced due to its multisensory nature as it involves visual, audio, and kinesthetic senses – where their combination has been shown to improve the associated memory (Ebert et al. 2009). When interacting with the EM, there is a barrier to entry for users in that they need to understand the interaction each time so that they can move appropriately. It has been observed that the amount of time it takes a user to realize an EM installation is interactive, in an unprompted environment, and the overall length of interactions the user will engage with EM depends on the users demographic. As a reference, children have been seen to engage with a single EM experience significantly longer than adults, whereas adults have been seen to have increased engagement time if the experience includes multiple triggers that allows them to transition between content quickly to explore the entire available set of EM. Depth cameras are seeing an increased demand after privacy and hygiene awareness rose and as EM offers a touchless solution, it is becoming increasingly attractive. Additionally, 3D cameras have the capability to work in very low lights and also in no-light environments like theatres and museums giving creators additional creative flexibility.

Exploring Innovative Technology: 2D Image Based Animation with the iPad

Jennifer Coleman Dowling
Communication Arts Department, Framingham State University, Framingham, MA, USA

E

Synonyms

2-dimensional animation; Innovative technology; iPad animation; Mobile devices

Definition

2D image based animation with the iPad is the process of developing new visualization and production methods with the use of a mobile device, while simultaneously providing theoretical and practical instruction of fundamental animation techniques.

Introduction

Teaching computer animation techniques using innovative approaches was made possible for me with two consecutive "Teaching with Technology" grants from Framingham State University. The goal of these grants is to enhance faculty competencies and improve student engagement. iPads were procured for inventive ways to learn digital animation and time-based media for artistic and commercial purposes.

In this entry, I will share how the use of technology has enriched and broadened the academic experience for students learning computer animation. I will also cover the goals and outcomes of this research, including student survey results, assessments, and animation examples. While learning to animate with iPads, students sketched ideas, brainstormed, planned narrative and storytelling structures, conducted research, and presented and shared their work. In addition, they had ongoing opportunities for collaborating with

one another on group projects, exchanging ideas, discussing work, and giving/receiving feedback.

State-of-the-Art Approaches

Complementary tactics with iPads included the studying of historical and contemporary figures in the animation field; sketching characters, scenes, and storyboards; manipulating timeline key frames and stage elements, and adjusting camera views; digitizing and editing audio tracks; and capturing and manipulating photography and video. They also digitized and edited audio tracks; and capturing and manipulating photography and video. The iPad is commonly used for *consumption*, such as watching videos and reading articles. It is not typically viewed as a tool for creating computer graphics and animation (Dowling 2012). In my project, iPads in addition to iMacs were used as tools to supplement the teaching of animation.

Summary of Work

The "Teaching with Technology" grant funding allowed me to explore new instructional approaches and inventive ways for students to learn digital animation and time-based media for artistic and commercial purposes. One objective was to minimize technical variables by utilizing identical mobile devices, so as to eliminate such problems as computer lab restrictions and lack of available software on laptops, and to encourage synchronicity. The iPads allowed students to use one primary device for learning new topics and completing projects in a timely manner, which provided the opportunity to adapt my way of teaching existing design theories to a new digital platform. They also exposed students to new concepts and helped to build their skill base with innovative tools (Davis 2012). Students were able to garner capabilities that would not be possible with the iMacs or laptops alone. The iPads also facilitated animation creation by giving students unlimited access to the same technology.

Overview of Creating 2D Animation on the iPad

The technological benefits to students were that the iPad provided them with tools to collaborate, experiment, and expand their skill set. It allowed students to develop new visualization capabilities and production methods while simultaneously providing the theoretical and practical instruction of fundamental animation techniques. It also facilitated a more imaginative process for solving problems, discovering inspiration, creating concepts, and exchanging ideas so they could more fully develop their knowledge of the subject while building more versatile computer animation capabilities. The technology that was distributed and available to students consisted of: iPads with retina display, stylus pens, protective cases with keyboards, and iPad stands. In the computer lab they had access to iMacs, Wacom digitizing tablets with stylus pens, a scanner, speakers, microphones, a large digital display, and Apple TV. Some of the apps that were provided and used on the iPads were: Adobe Ideas (vector drawing), Adobe PS Express (photo editor), Animation Creator (frame-by-frame animation), Animation Desk (high end animation), CELTX Scripts (screenwriting), CELTX Shots (storyboarding), DoInk (character animation), Flip Boom Cartoon (digital flipbook), GarageBand (audio creating, recording, and editing), iMotion (stop motion animation) and Stop Motion Studio (stop motion animation), and Storyboards (narrative storytelling).

There were advantages to teaching animation with mobile devices, which included: the minimizing of technical variables by utilizing identical mobile devices; allowing students to conduct ongoing research, write, create, record ideas, take notes, access course content, present and share work, and collaborate using one device, so as to learn new topics and complete projects in a timely manner.

Assessment tools were used to monitor what students were learning. They were beneficial as a means of informing pedagogical decisions. The following assessment tools were used: surveys at

the beginning and end of the semester, rubrics for grading project assignments, journal for understanding the learning process, and self-evaluations and critiques. Students were also asked to write in a journal every three weeks and these entries were only shared with me. Questions included: What are your initial thoughts about the course with respect to the technology provided? How has your project development evolved (i.e., research, concepts, current progress, software covered)? What are you learning, how are you learning it, and what do you want more (or less) of at this point in the semester?

Students were also given surveys to fill out at the beginning and end of the semester. Some of the final exit survey questions were: Do you use the iPad or a computer for viewing examples and animation videos, and participating in discussions? Has the iPad been an asset or a hindrance in your learning of animation? How does using an iPad for creating animation compare with the Mac?

Experiments and Examples

Projects that my students worked on and topics they experimented with included: researching animators, critical analysis presentation, storyboards and scripts for narrative storytelling, digital audio and video recording and editing, introductory logo sequences, and web banner ads, kinetic typography, character animation, stop motion animation, social cause animation (public service announcement), and photographic manipulation with iPad apps and iMac software. Examples of some of the student animations can be found on my YouTube channel: https://www.youtube.com/channel/UCepa8uuWVj5H0-19yuFUoEw (Figs. 1 and 2).

Exploring Innovative Technology: 2D Image Based Animation with the iPad, Fig. 1 Students working in Animation Studio Fall 2013

Exploring Innovative Technology: 2D Image Based Animation with the iPad, Fig. 2 Examples of student work from computer animation techniques class

Conclusion and Goals

Success when teaching with iPads included: iPads for sketching, storyboards, planning narrative sequences, conducting research, demonstrating techniques, presenting work; stylus pens for drawing and general use; student surveys; Blackboard for communication and posting course material; Dropbox & Google Drive for project submission and file storage; student interaction: exchanging ideas and assisting each other in class; apps on iPad: FlipBook, DoInk, Animation Creator, GarageBand, and iMotion.

My future goals and approaches to technology include more interaction outside of class using iPads and/or other social media approaches, inviting visiting lecturers (live or via Skype), mobile classroom both on and off campus, students demonstrate techniques to classmates on large display and/or gather in small groups, Blackboard collaborate sessions for virtual office hours, FaceTime for one-on-one assistance, eBook required in addition to web resources, voice dictation for my comments and for students posing questions, video capture for teaching how to use software (uploaded to Blackboard), sharing ideas on class blog so as to keep ongoing dialogue, group work and collaborative projects, YouTube and/or Vimeo uploads for regular online presence, social media conversations/interactions/sharing (Google Communities, Facebook, or Twitter).

Eye Tracking in Virtual Reality

Mehmet Ilker Berkman
Communication Design, Bahçeşehir University Faculty of Communication, Istanbul, Turkey

Synonyms

Foveated rendering; Gaze prioritized graphics; Gaze tracking; Gaze-contingent displays

Definitions

Eye tracking techniques have many applications of research in medicine, psychology, marketing, and human factors. It is also used as a human–computer interface for applications such as gaze-based typing and communication (Majaranta 2012; Ten Kate et al. 1979), driving safety (Chen et al. 2018; Grace et al. 1998; Kutila et al. 2007; Sinha et al. 2018), and gaming (Smith and Graham 2006; Tobii Gaming n.d.). Besides being a research tool and human–computer interface in VR (virtual reality), gaze-based techniques are also used to enhance the graphics quality and performance of displays with methods of gaze prioritized graphics, also known as foveated rendering. Furthermore, statistical models of eye tracking data are employed to provide eye movements for computer-generated avatars (Gemmell et al. 2000; Seele et al. 2017; Vinayagamoorthy et al. 2004).

The human sight is limited to 135° vertically and 160° horizontally, but the detailed sense of vision occurs only within a 5° central circle which is projected to fovea centralis (or fovea), the retinal region tightly packed with color cone receptors. By detecting the movements of the eye, it is possible to distinguish its rapid movements from longer fixations to detect a person's point of regard.

There are four techniques mainly used for measuring eye movements (Duchowski 2017: 49–56). Electro-oculography (EOG) is based on sensors around the eye that measures changes on the skin conductance due to eye movements. Another technique uses scleral contact lenses that usually employ a search coil that produces electromagnetic signals. Photo-oculography (POG) and video-oculography (VOG) techniques are less invasive since they require investigation of state of the eye visually. These techniques are slightly different from the video-based combined pupil and corneal reflection, as they do not only measure eye movements, but also measure the size of the pupil and position of limbus. Unlike the other three techniques, the video-based combined pupil and corneal reflection method does not require users' head to be fixed, since it captures the

corneal reflection of a light source relative to the position of pupil. The relative positions of the corneal reflection and pupil indicate the user's gaze direction. For example, if the corneal reflection is below the pupil, the gaze direction of the user is directed above the camera (Poole and Ball 2006). The corneal reflection is usually acquired using infrared (IR) light sources. The video-based combined pupil and corneal reflection technique is broadly used in the contemporary eye tracking devices, including the VR equipment with eye tracking capabilities.

Two primary measurements used in eye tracking research are fixations and saccades. Fixations are stabilization of retina over a stationary object of interest. Saccades are rapid eye movements used in repositioning the fovea to a new location in the visual environment. These movements can be voluntary in order to switch between objects of interest. Otherwise, they can be smooth pursuits which are invoked as a corrective optokinetic or vestibular measure. The vestibular smooth pursuits occur due to the head movements of the observer while optokinetic pursuits are interspersed with saccades invoked to compensate for the retinal movement of the target. In the context of gaze-contingent system design, the identification of fixations, saccades, and smooth pursuits is a primary requirement (Duchowski 2017: 39–46).

The eye-movement based research has its historical roots in cognitive research on reading (Rayner 1998). Although the characteristics of eye movements differ across different tasks such as reading, scene perception, and visual search (Rayner 2009), the fixation of the gaze can be considered as "the top of the stack" of the cognitive processes, the focus of attention (Just and Carpenter 1976).

Duchowski (2018) categorized gaze-based interactions into four: diagnostic, active, passive, and expressive. The diagnostic methods use offline measurement of eye movements for research purposes, training, or assessment of expertise. Active methods use real-time eye tracking data as a human–computer interface for selection tasks or inputs based on gaze gestures. Passive methods utilize eye tracking in gaze-contingent displays for foveated rendering, manipulating the scene elements in response to gaze direction. The expressive use of gaze-based interactions may utilize real-time or prerecorded eye tracking data besides algorithms for synthesizing eye movements of virtual avatars.

Eye Tracking in Context of Virtual Reality

The studies considered here were selected with a focus on eye tracking applications combined with VR systems, but eye tracking studies in other fields that contribute to VR were also considered. As the VR mainly depends on 3-D (3-dimensional) virtual worlds, the methods which are integrating 3-D objects and eye tracking are mentioned, followed by a brief review of gaze-based interaction work in VR according to the taxonomy of Duchowski (2018). The scope of VR is limited to HMD (head mounted display) and CAVE (cave automatic virtual environment) systems.

Estimation of Point of Regard in Three-Dimensional Spaces

Rötting et al. (1999) used a scene camera along with the eye tracking cameras to determine the point of regard in the 3-D real world, using a two-step offline process. At the first step, at least two views from scene camera are used to detect the contours of the object in the real world to create a geometry model that approximates object in the space. At the second step, the fixations mapped on the image of the scene camera were classified on each frame that the observed model was determined. Methods used in VR reality follow a similar approach. Using HMDs, where the content is already being described by geometries, the systems could directly use the projection rendered for the particular eye from the framebuffer (Pfeiffer 2012). As the eye position to the display is fixed, the detected position of the eye on the display can be used to cast a ray into the 3-D world to detect collisions with 3-D object geometry (Duchowski et al. 2000, 2002). The methods using this geometry-based approach assume that the first object that the casted ray intersects is the point of regard. Monocular eye tracking is sufficient for

geometry-based approaches but binocular eye tracking enables detecting the vergence of the eyes to estimate fixation depth (Pfeiffer et al. 2008).

Uses of Eye Tracking in VR

Diagnostic Use and Visualization of Gaze Data

Duchowski et al. (2000) developed an HMD with eye tracking capabilities to track the users' eye movements in a virtual aircraft cargo bay training system. Their work is an early application of matching user's gaze direction on a planar surface with the polygonal 3-D virtual environment (Duchowski et al. 2002). The diagnostic use of eye tracking, such as in usability studies, require the visualization of gaze movements in forms of attentional maps (or heatmaps) that represent the density of fixations or as scanpaths that describe saccade-fixade-saccade sequences. Blascheck et al. (2017) reviewed these methods as point-based and area-of-interest based methods. Point-based methods of analyzing 3-D data were proposed for nonstereoscopic 3-D games (Ramloll et al. 2004) or real-world environments mapped into 3-D computer models (Paletta et al. 2013). Several area-of-interest-based methods are proposed for visualization of real-world eye tracking data (Baldauf et al. 2010; Itoh et al. 1998, 2000; Schulz et al. 2011; Tsang et al. 2010) with an exception of work by Duchowski et al. (2002), which is a pioneering use of eye tracking in virtual reality. The studies that include both point-based and area-of-interest-based methods provide techniques for real-world settings such as flight simulator cockpits (Weibel et al. 2012) as well as 3-D virtual environments. Stellmach et al. (2010) proposed three methods for 3-D attentional maps that are applicable to VEs (virtual environments). Projected attentional maps are 2-D planar representations of 3-D fixation data. Object-based attentional maps represent models' attractiveness by assigning a color on its whole textural surface. Surface-based attentional maps depict aggregated fixation data directly on the textural surface by attributing gaze positions on mesh triangles of models. Pfeiffer (2012) established a holistic approach to collect and visualize eye tracking data on both real-world objects and virtual environments. His method provides a volume-based modeling of visual attention. Later, Pfeiffer and Memili (2016) developed "attention textures" as a method of representing gaze fixations on 3-D objects.

Active Use of Eye Tracking in VR as a Control Interface

Mine (1995) described gaze-pointed selection among the other interaction methods. A drawback in gaze-based interfaces is the Midas touch problem, i.e., the unintentionally activated commands while the user looks at an interactive element (Jacob 1995). Tanriverdi and Jacob developed a system (2000) to compare the gaze-based interaction to point-based interaction and revealed that gaze-based interaction is efficient in a virtual environment explored via HMDs, especially to interact with distant objects. Pfeiffer (2008) with Haffegee and Barrow (2009) developed systems that employ gaze input to interact with objects in CAVE-like environments, defining a ray-casting approach to transform users' gaze into 3-D environment. Greenwald et al. (2016) manufactured a cardboard VR system with eye tracking capability for user interactions.

Gaze can be used as a "lazy" method to eliminate and minimize hand movements, as a "helping hand" to extend existing hand-based interactions, or "hand down" methods in which gaze provide a context in VR for an additional hand-held device such as a tablet computer (Zeleznik et al. 2005). Novel interaction methods can be evaluated within the context of these three classifications, e.g., duo-reticles, radial-pursuit, nod and roll (Piumsomboon et al. 2017) as "lazy" methods, or gaze + pinch (Pfeuffer et al. 2017) and VRpursuits (Khamis et al. 2018) as "helping hand" approaches.

Currently, there are several HMDs with eye tracking capabilities on the market, which provide software development kits and add-ons for different VE development platforms to transfer user's gaze direction for interacting with objects in the 3-D environment (Hollomon et al. 2017).

Passive Use of Eye Tracking in VR for Gaze Prioritized Graphics

An early suggestion to use eye tracking for rendering gaze prioritized 3-D graphics described several computational methods (Ohshima et al. 1996), but it is not clear that the proposed system is a simple prototype at proof-of-concept level or a head-mounted display with working eye tracking capabilities. Former studies (Iwamoto et al. 1994) suggested using mechanical/optical solutions for foveated rendering on HMDs. Duchowski et al. (2000) applied several algorithms to match gaze direction with polygonal 3-D objects. Those algorithms evolved into gaze prioritized rendering methods (Murphy and Duchowski 2001). The latency of eye trackers had been an issue in foveated rendering (Triesch et al. 2002), and research revealed that "foveated rendering is tolerant to eye-to-image latencies of about 50–70 ms, beyond which it is easily perceived and hence loses effectiveness" (Albert et al. 2017). Current research focuses on the comparison of different foveated rendering techniques in terms of hardware performance and user perception (Albert et al. 2017; Pohl et al. 2016; Swafford et al. 2016; Roth et al. 2016).

There are two objectives of gaze prioritized methods: increasing the rendering performance and increasing user comfort (Duchowski 2018). The speed of rendering is increased by freeing up the computational resources through matching user's "retinal and visual acuity resolutions" with the resolution of the area viewed by the user, leaving the nonfoveated areas rendered in a lower resolution. To achieve this, model- or pixel-based approaches can be followed. Model-based approaches employ polygonal simplification (Levoy and Whitaker 1990; Luebke and Erikson 1997; Luebke and Hallen 2001; Zha et al. 1999) by controlling the level of detail in polygonal objects. Current research focuses on enhancing the algorithms and optimizing the rendering field to improve the image quality perceived by users (Patney et al. 2016; Pohl et al. 2016; Roth et al. 2017; Weier et al. 2016).

The pixel-based approach focuses on spatial and temporal complexity of pixel data just prior to rendering, e.g., decreasing resolution or color depth (Watson et al. 1997). Recent research exploits this approach to vary the streaming video bit rate according to observer's gaze (Arndt and Antons 2016).

A hybrid of both object-based and pixel-based methods have also been explored (Murphy et al. 2009).

The research on increasing user comfort of stereoscopic displays utilizes gaze-contingent rendering to simulate depth of field (Kellnhofer et al. 2016; Duchowski et al. 2014). Typically, the human eyes converge and accommodate at the same point; but in 3-D displays, convergence occurs in front of or behind the screen, where the image forms while the accommodation occurs on the surface of the flat screen. This accommodation-vergence conflict often leads to a discomfort in viewers of stereoscopic displays (Mon-Williams and Wann 1998) and it is one of the reasons of cybersickness (Carnegie and Rhee 2015). To overcome this problem in VR, objects in the 3-D world that do not lie on the convergence point of user's eyes are blurred to simulate real-world depth of field.

The passive gaze-contingent techniques also employ methods that estimate the gaze movements and fixations, to overcome the latency which occurs between eye tracking and rendering (Arabadzhiyska et al. 2017; Kulshreshth and Laviola 2016). Some research focuses on employing models of estimation without using real-time eye tracking input, employing saliency maps (Advani et al. 2013; Swafford et al. 2016), or using machine learning methods to predict the important objects (Koulieris et al. 2015, 2016). Lavoué et al. (2018) compared 3-D eye tracking results and several saliency mapping algorithms and detected that algorithms still remain poor at predicting fixation locations.

Expressive Use of Eye Tracking in VR

The real-time eye movements of user captured via eye tracking, prerecorded eye tracking data, or algorithms developed to synthesize the eye movements are used to increase realism of avatars or virtual characters, as well as to increase the perceived quality of communication in a shared virtual environment. The visual deictic reference

enslaved to users' gaze found to be enhancing the trainee performance in collaborative VEs using HMDs (Duchowski et al. 2004; Sadasivan et al. 2005). In a multiparty object-focused puzzle scenario conducted on a CAVE-like environment (Steptoe et al. 2009), the tracked gaze was observed as the highest performing condition. Murray et al. (2009) implemented an avatar-based video conferencing for CAVE-like VR systems that supports eye tracking and they evaluated the role of gaze in remote communication. Recently, Roberts et al. (2015) implemented an eye tracker in their end-to-end telepresence system.

Duchowski (2018) criticized the method of mapping prerecorded eye movements to a virtual character as it is costly since this method requires an actor for every recording while eye tracking devices inject noise to eye movement data during recording. Alternatively, synthetic eye movements are employed in development of virtual characters and humanistic robots, which involve modeling saccades, smooth pursuits, binocular rotations implicated in vergence, coupling of eye and head rotations, pupil dilations and constrictions, and microsaccadic jitters during fixations (Duchowski and Jörg 2016).

Face Beautification in Antiage

Sun Ruoqi and Lizhaung Ma
Shanghai Jiao Tong University, Shanghai, China

Synonyms

Face makeup; Face skin and shape beautification; Reversed face beautification

Definition

Face beautification in antiage is a technology of making human face beautiful based on the reversed aging revolution, which means that the algorithm produces a more beautiful face by changing the texture and shape of the original human face.

Introduction

Face beautification is an essential research topic in the image process and computer graphics, which contains dozens of algorithms based on 2D or 3D human faces. The process of 2D image is generally divided into two directions. Furthermore, the main idea of beautification method is to smooth textures by using the special filter and to change the geometry of face shapes by using designed warped projections. The rise of the 3D print technology promotes the development of the beautification methods of 3D scans, most of which concentrate on face shape beautification. Due to the great effect that it has in feature extraction and expression, deep learning improves the results of beautification by matching the features of input faces to the attractive ones based on the theory that faces combined with the good features of beautiful faces have the perfect appearance. Currently, numerous companies focus on accelerating the research and development of human face beautification applications.

There is a widespread knowledge that the younger face with less wrinkles is more attractive. Face makeup is one of the most effective methods to enhance a person's appearance, which can also make the face younger. Furthermore, medical technologies have developed rapidly; thus, an increasing number of people have cosmetic surgery to achieve the younger effect. Although a number of celebrities benefit from it, many people failed due to the high risk of the surgery. It is worth for some people to take the risk, while it is not necessary for most of other people. But we cannot deny that everyone would like to be more beautiful on photos. As technology progresses, it is convenient for people to increase the quality of photos by using image post-processing technology. Face beautification in antiage attracts growing attention in the image processing field, which generates numerous algorithms.

In this entry, we do a survey and introduce the present work in face aging, aesthetic plastic technology, and reversed age face beautification.

State-of-the-Art Work

Many researchers have been exploring in the image processing field, and they constantly improve face beautification algorithms based on the face aging rule. Firstly, we introduce the present face aging algorithms, which are related to the face beautification methods. Secondly, we briefly survey the plastic technology to explore the mysteries of facial aesthetics. Finally, we discuss the reversed age face beautification algorithms (Fig. 1).

Face Aging

Facial aging algorithm is mainly used in cross-age face recognition, entertainment, and other fields. The main idea of the algorithm is to add age features to the young faces without changing the identity characteristics. Traditional methods, respectively, change face textures and shape (Ramanathan and Chellappa 2006; Kemelmachershlizerman et al. 2014; Shu et al. 2015). In 2016, Wang proposed recurrent face aging (RFA) framework based on RNN to generate the aging face which produced more natural results (Wang et al. 2016). However, this method can only generate younger face stage by stage, which cannot produce older faces across the stage. Generally, the human face aging process has close relationship to wrinkles and shapes (Fig. 2).

Aesthetic Plastic Technology

With the improvement of medical technology, people can change their face texture and shape to make a younger and more charming face by having aesthetic plastic surgery. In 1962, Gonzalez-Ulloa M put forward the principle of aesthetic plastic (Gonzalez-Ulloa 1962). Therefore, cosmetic technology has been receiving increasing attention. A large amount of cosmetic methods have been proposed, such as antiaging plastic

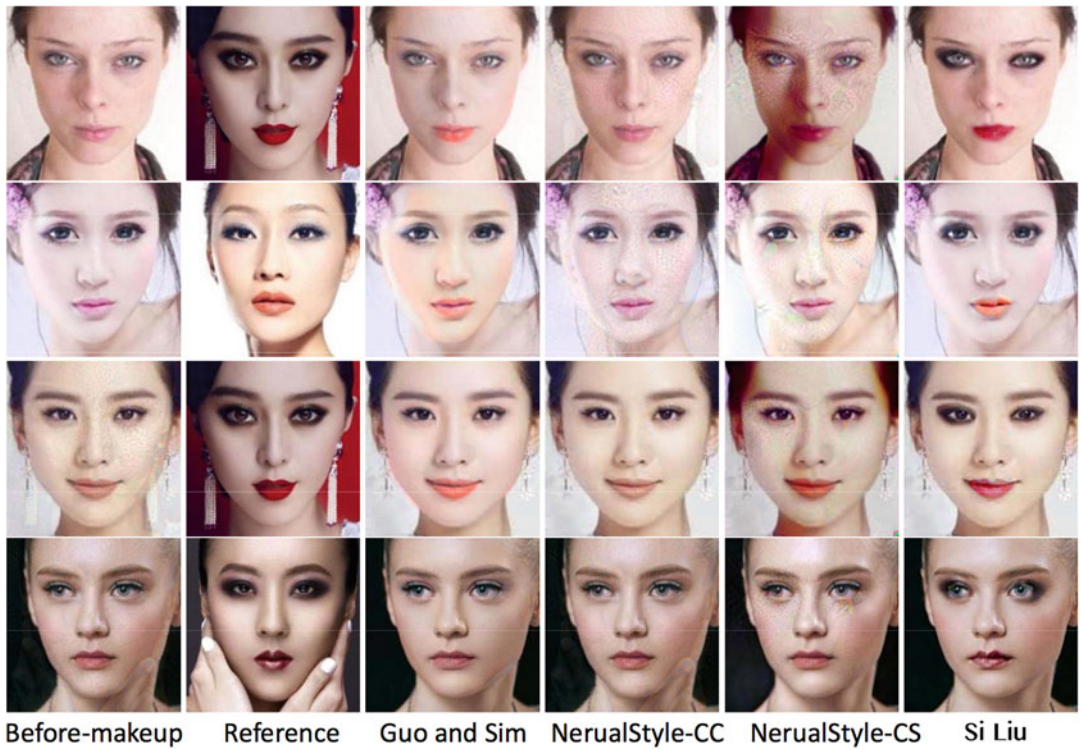
Face Beautification in Antiage, Fig. 3 The Marquardt mask (Stephen 1997)

surgery (Giampapa et al. 2003), double eyelid surgery (Song and Song 1985), etc. What's more, Brennan proposed a method to beautify the skin (Brennan 2015). There are dozens of specific methods to make you look more beautiful. Some of these patients would like to have a more symmetrical face. As mentioned above, Liu Fang did the research and showed that the symmetrical face is more charming (Liu 2010). Thus, morphing the face toward symmetry properly can improve the face' attractiveness. But this is only one general rule, while there are also some

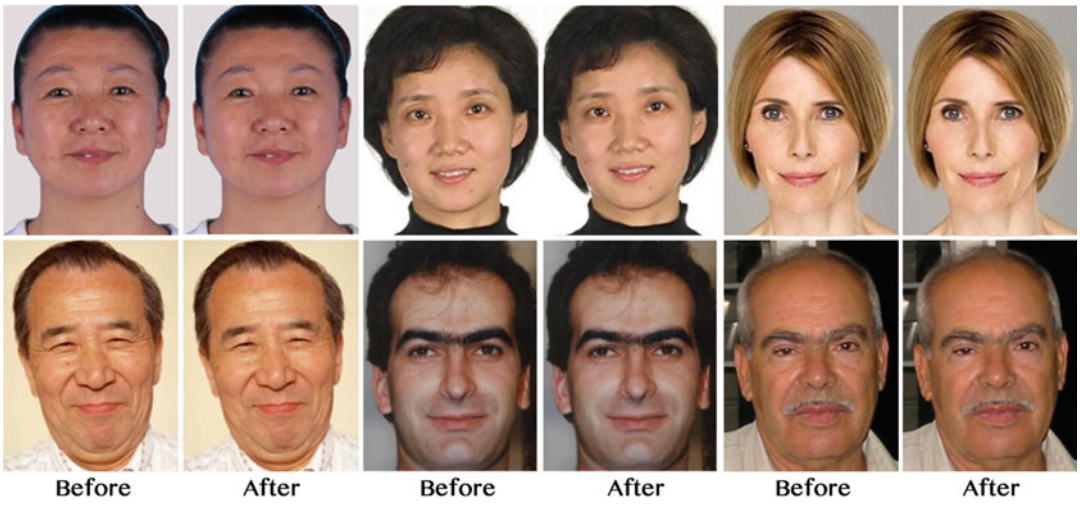
asymmetric faces which are more beautiful. Others who aim to change the shape of their face usually choose an attractive star as the target or look for a generally accepted face. At this time, most of the doctors would choose the Marquardt mask, which is the standard face of the aesthetics. The Marquardt mask is also called the golden face for that it conforms to the golden ratio. When the person who is older than 20 years old grows up, the face shape would go far from the Marquardt mask, which also means that the face aging has great effect on the attractiveness of human faces (Fig. 3).

Reversed Age Face Beautification

In recent years, face beautification in antiage algorithm has made unprecedented progress in the image processing field. Face texture is affected by five characters, such as spots, wrinkles, puffiness, dark circles, and shapes. In the real world, people change these characters by using cosmetics, while there are corresponding algorithms in image processing area. There are lots of company proposing the applications to achieve the demand of consumers, such as Microsoft, Facebook, Apple, Tencent, etc. Other algorithms are presented to learn the age features and apply the reversed aging features directly to beautify human faces. In 2013, Chen use standard deviation to extract the age feature and get younger face by training SVM (Chen et al. 2013). In 2015, Sun proposed a method to replace the aging skin with neighbor skin with younger features, which produce younger faces without losing the identical features (Sun et al. 2015). Deep learning developed rapidly which promotes the development of the skin texture beautification. In 2015, Li learns the features which are related to beautification by using deep learning to generate beautified faces (Li et al. 2015). In 2016, Xi Lu proposed a framework focused on skin beautification based on layer dictionary, which is good at removing facial



Face Beautification in Antiage, Fig. 4 Face makeup examples (Liu et al. 2016)



Face Beautification in Antiage, Fig. 5 Face beautification examples (Sun et al. 2015)

wrinkles and spots (Xi Lu et al. 2016). These algorithms focus on different aspects and have achieved great results (Figs. 4 and 5).

Conclusion and Discussion

Facial beautification algorithm develops rapidly; there are many companies that invested a great deal of resources for in-depth study. A variety of face beautification algorithms are proposed recently. Increasingly importance has been attached to the face beautification method in antiage since it protects the personality of human faces in the beautification process. There are many applications that can beautify face in real time, but these algorithms still have to be improved, such as promoting the sense of reality and removing the age characteristics. Face beautification algorithm in antiage would have great development in the future.

Definition

Real-time detection and analysis of facial recognition and emotion states is a technique that offers methods and processes for the control of media content, communication via interactive experiences and social media.

Introduction

Facial recognition technology is a growing area of interest, where researchers are using these new applications for study in psychology, marketing and product testing and other areas. There are also applications where the use of facial image capture and analysis can be used to create new methods for control, mediation, and integration of personalized information into web based, mobile apps, and stand-alone systems for media content interaction. Our work explores the application of facial recognition with emotion detection, to create experiences within these domains. For mobile

media applications, personalized experiences can be layered personal communication. Our current software implementation can detect smiles, sadness, frowns, disgust, confusion, and anger (Database FERET). In a mobile media environment, content on a device can be altered to create fun, interactive experiences, which are responsive and intelligent. By intersecting via direct communication between peer to peer mobile apps, moods can be instantly conveyed to friends and family – when desired by the individual. This creates a more personalized social media experience. Connections can be created with varying levels of intimacy from family members to close friends out to acquaintances and further to broader groups as well. This technique currently uses pattern recognition to identify shapes within an image field using a Viola and Jones (2001) Haar-like feature detector, OpenCV (Bradski and Kaehler 2008), a "Feret" database (Chang and Lin) of facial images, and a support vector machine library (LibSVM)(Burges 1998; Bolme 2003) to process video or images from a web camera and to identify if a face exists. The system processes the detected faces using an elastic bunch graph matching (Hlang 2012) technique that is trained to determine facial expressions. These facial expressions are graphed on a sliding scale to match the distance from a target emotion graph, thus giving an approximate determination of the user's mood.

State-of-the-Art Work

Currently, many media artists are using vision systems, sensor-based systems, and other technologies to create interactive experiences and mediated arts works in public spaces. In many of these works, the images are projected onto building facades or use embedded LED arrays on building surfaces. In Asia, it is common for newer buildings to use vast LED arrays on the façade of the building. These projections and LED arrays can use video playback, images changing over time or other ways to control the imagery. Our work focuses on the possible use of vision systems for the face detection and facial recognition, which then can be used to control or mediate visual information on surfaces in public spaces or to allow mobile apps and web-based experiences and through social media.

Overview

Considering historical examples, artists have explored the use of projected imagery or light works as a primary medium. These works may fall into one or more genre or may be in between different genres of art. Looking at examples of installation, or environmental art works, the work of Dan Flavin (https://chinati.org/collection/danflavin.php) is exemplary in the use of light as a singular imaging medium. Flavin's work, as he has described it, is created and experienced in a strict formalist approach. Formalism focuses on the way objects are made and their purely visual aspects. Nevertheless, the works, such as Flavin's, though static light alter or inform audience spatial perception of spaces where they are installed. In our study of the use of interactive elements, can the viewer's perception be altered by the shifting of color or imagery based on responses detected from the viewers themselves? Further, can we use the detection of subtle emotional cues to alter the qualities of the imagery or installation? More recently, the projection of video or animated imagery on building facades or in public spaces has become a common way to attract viewer engagement. In these types of new media art work experiences, such as the 2011 transformed façade of St. Patrick Cathedral and the New Museum in New York (http://www.newmuseum.org/ideascity/view/flash-light-mulberry-street-installations, these altered architectural and public spaces become a "canvas" where images and media content can be viewed outside of the special circumstance of the gallery or museum. Considering possible ways to allow for audience interaction, we know that sensors and vision systems are being used to encourage audience participation. Can subtle emotional cues be used as well?

Facial Recognition for Artistic, Environmental Installation in public Space

Detection of emotion states in a public art installation to change the environmental elements is possible. Using webcams positioned in specific selected locations can capture facial information, the emotion states can be detected. The detected state can be used to alter projected imagery, auditory ambiance and ambiance of lighting, intensity and color. The location of the camera need not be directly within the installation space. Indeed, the control of the qualities of the imagery, lighting, or ambiance can be collected remotely in other building location, from the Internet and even by mobile apps (Fig. 1).

In my work, "MoodModArt," and the subsequent system "MoodRing," we use emotion detection to change the quality of an image based on detected moods (Fig. 2). "In MoodModArt," detection of the seven basic emotions states (Ekman 1999) enables responses in the imagery as a results of the emotion detected. The seven basic emotion states as defined by Eckman are the states used for training and detection in "MoodRing."

If the detected emotion of a viewer is positive, the streamed loop of video is vibrant and colorful. If the detected emotion is negative, the streamed loop of video played to a drab and darker view. The viewer can change quality of the image by altering their facial expression Fig. 3.

Facial Recognition in Mobile Apps, Internet Webpage Detection, and Stand-Alone Kiosk Systems

In mobile apps, detected emotions of a viewer can be shared via social media through simple #hashtag or Facebook posts. Using HTML5/CSS3 along with Canvas, apps, and webpages can be used to capture and submit an image to a back-end server application, which returns a detected emotion state. Apps and webpages submit an image to a cloud database. The server listener application listens for images arriving, tagged with random user IDs and time stamps. The listener passes the image to a back-end server application, which returns a detected emotion state to the listener. The listener then returns the result to the webpage or app (Fig. 4).

Developmental Work in Facial Recognition: Gender and Age

Our work in facial recognition began with experimentation with the detection of gender and age in public spaces. In our earlier project "HiPOP," we were successful in implementing a software tool for facial recognition for use in public spaces. The

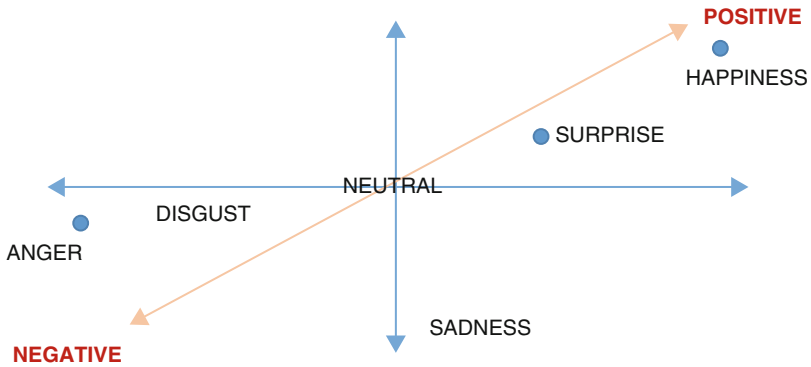
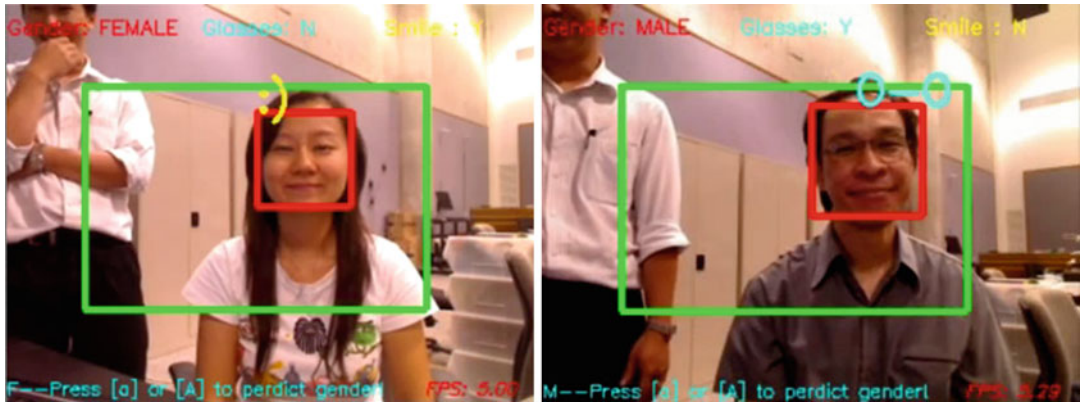
Facial Recognition and Emotion Detection in Environmental Installation and Social Media Applications, Fig. 3 Graphing of emotion states on a continuum from negative to positive



Facial Recognition and Emotion Detection in Environmental Installation and Social Media Applications, Fig. 4 Transfer of captured images to a server application and the return of a detected emotion

focus of this work revolved around the detection of gender and age. This implementation uses an image processing approach by identifying shapes within an image field using methods published by Viola and Jones (2001). The technique employed a Haar-like features application (Viola and Jones 2001; Burges 1998) and a "Feret" database (http://www.nist.gov/humanid/colorferet; Chang and Lin) of facial images. A support vector machine (LibSVM) (Burges 1998) was used to classify the faces to glean attributes such as gender, age, and other individual characteristics. The system segmented the captured image to recognize face rectangles. The detected face area is scaled to a



Facial Recognition and Emotion Detection in Environmental Installation and Social Media Applications, Fig. 5 Detected genders invoke playback of targeted media

64 × 64 pixel grayscale image and an equalized histogram is used to increase contrast. The OpenCV (Bradski and Kaehler 2008) library was used to detect and segment faces from video images through the following methods:

1. Using a cascade of boosted classifiers working with Haar-like features.
2. Training classifiers by a database of face and nonface images.
3. Scanning input images at different scales to find regions that are likely to contain faces.
4. A SVM classifier method using data points as a p-dimensional vector was used to detect smiles in the captured images, where p is the number of feature pixels in the image.

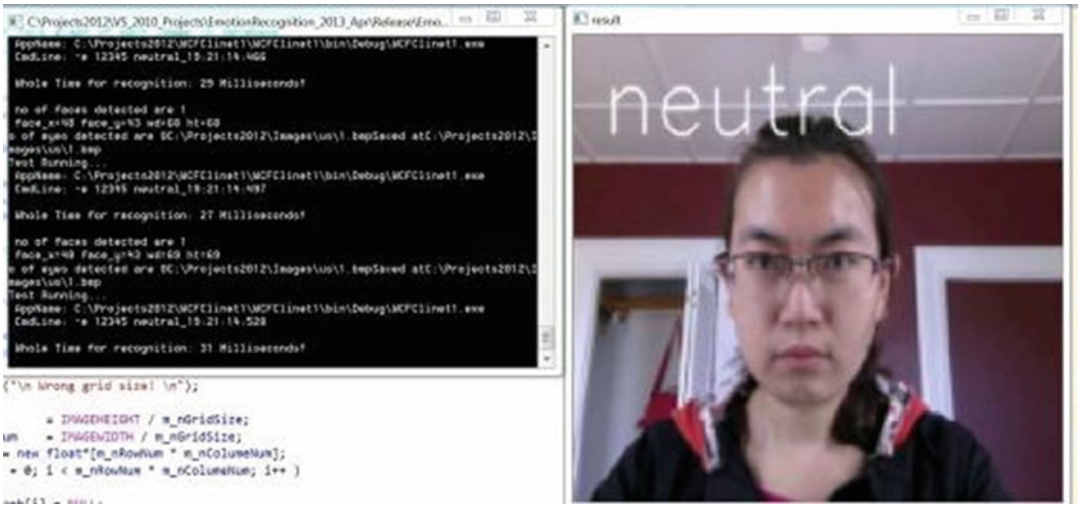
Application of such a system is feasible in environments where marketing messages can be targeted for individuals based on gender, age, or other cues that can be identified. The design of the system installation allows marketing or media content to be played based on the detection of certain demographic information detected from consumers in a retail environment (Fig. 5).

Development of Emotion Detection: Emota v1.0

Work on emotion detection in the initial stages used a hybrid approach with a library of images, each with an elastic bunch graph match (EBGM) (Wiskott et al. 1997; Hlang 2012). The software implementation was designed with two modules to process the captured video images and give the resulting detected emotion. The "ImageNormalizer" module detected the face from an image, cropped, resized to a standard size (90 × 100 pixels), and converted these to grayscale. The normalized image was input to the EBGM program. Training for detection of emotion states in an individual was required for accuracy. The technique used a database of filtered images defined with an index set that were identified as one of seven emotion states. The "EmotionRecognition" module integrated with "ImageNormalizer" so that every captured frame was normalized and the detected face was stored in normalized form on the fly. "EmotionRecognition" used EBGM with the on the fly normalization program to output a detected emotion state from the captured image (Fig. 6).

Development of Emotion Detection: Emota v2.0 (Mood Ring)

Additional work in the detection of emotion has continued with the version 2.0, entitled "MoodRing." This implementation has four modules: MoodRing MFC, MoodRing Core, Weight Trainer, and Database Compressor.



Facial Recognition and Emotion Detection in Environmental Installation and Social Media Applications, Fig. 6 A screen capture of Emota v1.0 in action

Both MoodRing MFC and MoodRing Core are implementations of the project's core part. MoodRing Core is the interface version which shows how to set up this project under different platforms. Weight Trainer is used to train weight of each anchor point to calculate similarity among subgraphs. Once a model is trained, elastic bunching graphs (Wiskott et al. 1997; Hlang 2012) can be stored and compared instead of images. Database Compressor is used to compress elastic bunching graphs by comparing, searching, and combing similar graphs based on the distance among them.

MoodRing MFC is a stand-alone MFC version which supports emotion storage, batch training, and emotion detection. There are two options for emotion storage: user emotion storage and batch emotion storage. Batch emotion storage allows user to parse batch amount of images to xml files and add these files to dataset of certain user. The batch module is designed mainly to train large amount of images in order to set up the default dataset which belongs to the default user (Fig. 7).

User emotion storage allows user to capture, extract, and store emotions to numeric values one by one using a web camera. To use this system, the user initiates the training and capture of emotion state facial expressions by instantiating "user emotion storage." The system prompts for the seven emotion state expressions, and the images are captured and accepted. Once the seven states are stored, the system is effectively trained for that user (Fig. 8).

User emotion detection allows real-time user emotion detection. This can be used as a control for interaction, media, and environmental elements.

Emota v2.0 Mood Ring Core and Data Processor

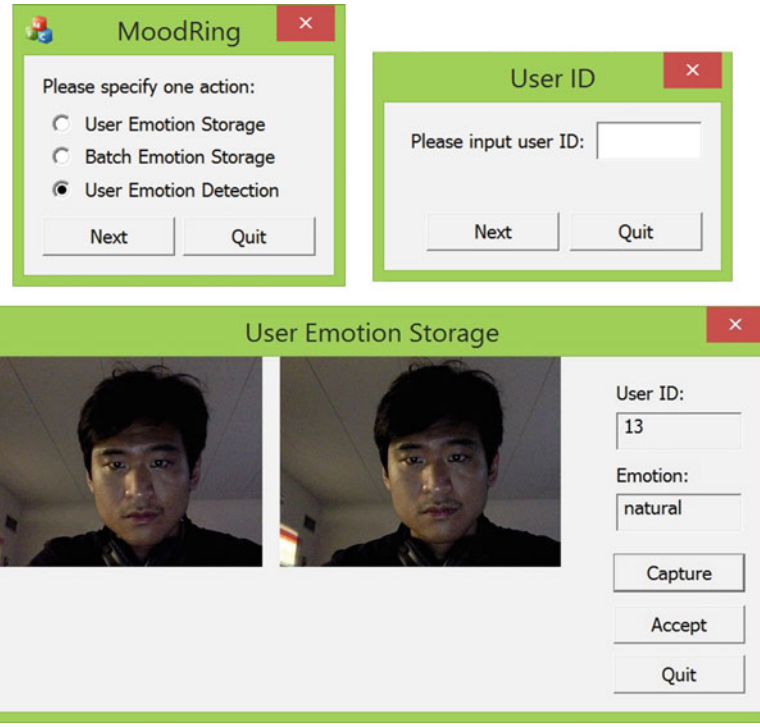
Image Preprocessing

First, we apply some image standardizations to get a small size gray scale image. Second, a series of image preprocessing operations are adopted, including noise removal and image balance.

Noise Removal (Ester et al. 1996). For each pixel, we calculate and accumulate the difference of all its neighbor points as the weight of this pixel:

$$\text{weight}(\text{x}) = K_1 e^{-K_2 \sum_{p \subset \text{P}} |f(p) - f(\text{x})|}$$

where P is the neighbor point set of pixel x, and f (x) is the pixel value of x.



Facial Recognition and Emotion Detection in Environmental Installation and Social Media Applications, Fig. 7 The interface windows for operation of MoodRing MFC

Facial Recognition and Emotion Detection in Environmental Installation and Social Media Applications, Fig. 8 Detected emotion states are stored in a periodic manner to a text file that is readable by other software, such as Max/MSP

Then, we traverse the image again with a weighted average filter for each pixel.

$$g(\mathrm{x}) = \alpha \frac{\sum_{p \subset \mathrm{P}} \mathrm{weight}(p) \cdot f(p)}{\sum_{p \subset \mathrm{P}} \mathrm{weight}(p)} + (1-\alpha) \cdot f(\mathrm{x})$$

Image Balance. We have noticed that vague shadow will not heavily affect Haar classifier performance, and hard shadow edges can heavily weaken performance. An image balance method is adopted such that useful information like edges is strengthened while noise like shadows is weakened. Thus, instead of complex shadow removal

algorithm, we adopt following operations to concentrate effective image information so that Haar classifiers can find target more easily:

$$f(\mathrm{x}) = \begin{cases} \alpha K \log(\mathrm{x}) + (1-\alpha)\mathrm{x} & , if\ \mathrm{x} < 127 \\ \alpha[255 - K\log(\mathrm{x})] + (1-\alpha)\mathrm{x} & , if\ \mathrm{x} \geq 127 \end{cases}$$

Face Detection

After above operations, we adopt a set of pretrained Haar classifiers (Wang et al. 2007) to locate only one pair of eyes and mouth (Alpers 2011; Messom and Barczak 2009). For facial detection, only eyes and mouth are used in this case. If multiple rectangles are found for the same part, we run a clustering method to estimate the target rectangle based on the Euclidean distance. We run a clustering algorithm based on Euclidean distance between locations of each possible candidate.

For example, to find one's left eye in all possible locations, say A, B, C, and D:

1. First, these possible eyes are clustered based on their locations and distance to each other. (A, B, and C are on the left side, while D is on the right side; A is near to B, while C is far from them. Then, we have {A, B}, {C}, and {D}.)
2. Then, clusters are selected based on their size and location with another eye. (If {A, B} are at similar vertical location as {D}, and symmetric to centerline of face about {D}, we choose {A, B} as left eye and {D} as right eye.)
3. Finally, location and size are calculated using {A, B} and {D}.

Then, a set of anchor points can be delivered based on these rectangles. Before feature extraction, lumen normalization is adopted to detected facial part of the image such that light conditions have less effect to the feature extraction process.

Feature Extraction

Numeric features are extracted through convolutions with a set of precalculated Gabor filters called Gabor Bank.

Gabor Bank

Gabor filters are implemented to derive orientations of features in the captured image using pattern analysis, directionality distribution of the features. Using Gabor filters increases accuracy of the anchor points derived in the elastic bunch graph matching. Gabor filters of all scales and orientations compose the Gabor Bank to detect edges and textures. In the Gabor filters:

$$\begin{aligned} g(\mathrm{x},y) &= \frac{k^2}{\sigma^2}\cdot e^{-\frac{k^2(\mathrm{x}^2+y^2)}{2\sigma^2}} \\ &\quad \cdot \left(e^{ik\begin{bmatrix}\mathrm{x}\\ y\end{bmatrix}} - e^{\frac{\sigma^2}{2}} \right), \text{where}\, k \\ &= [k_v\cos\varphi k_v \sin\varphi], k_v = 2^{-\frac{v+2}{2}}\pi \end{aligned}$$

where σ is the standard deviation of Gaussian envelope, φ is the direction of Gabor stripes, and v determines the wavelength of Gabor filters.

We choose 18 Gabor filters with six directions and three phases to compose a Gabor Bank.

Directions include:

$$\left|0, \frac{1}{6}\pi, \frac{1}{3}\pi, \frac{1}{2}\pi, \frac{2}{3}\pi, \frac{5}{6}\pi;\right.$$

phases include:

$$\left.C\pi, C\sqrt{2\pi}, C\sqrt{3\pi}\right|,$$

where C is a constant. Such a Gabor Bank will be initialized when the program starts, and used every time extracting features.

Elastic Bunch Graph

Operations of elastic bunching graph include graph matching, graph pruning, and adding subgraphs from either an image or an xml file. Elastic bunching graphs apply convolutions of certain areas of images using all filters in the Gabor Bank. This results in a list of anchor information for all anchor points, where each anchor information contains a list of all convolution results corresponding to filters in the Gabor Bank. If the

program is in a training mode, it will store the hierarchical results as an xml file. Otherwise, emotion detection is followed after feature extraction.

Graph pruning is the core function of Database Compressor. The pruning algorithm is basically a variety of DBSCAN (Ester et al. 1996), where the distance of subgraphs defined as sum of Euclidean distance of all convolution results for all anchor points. If one cluster contains at least the minimum number of neighbor point subgraphs, and distances of these subgraphs are at most eps, we combine all subgraphs in one cluster into one. Thus, very similar subgraphs are merged to reduce storage space and comparing time. Emotion Detection.

The emotion detection is a similarity comparing process. Target graph is compared with all subgraphs in all seven emotions (Database FERET) in the FERET dataset. We categorize the target graph for the same emotion type as its most similar subgraph. In comparison of two graphs, we can calculate a weighted average on the distance of all such convolution results of all anchors in graphs. When the program is initialized, a mathematical model determined by Weight Trainer is loaded, such that the weight of each anchor can be used to measure graph similarity (Fig. 9).

There are two types of preloaded dataset used in the detection process: default graph set and user graph set. When initialized, the program will load the default graph set, which only contains graph of the default user. As mentioned above, dataset for the default user is usually trained in the Batch Emotion Storage module. Since default user's dataset contains large amount of samples from existing database like "Feret" (http://www.nist.gov/humanid/colorferet, it can be used without user graph set. However, user graph set is still a better choice because it contains fewer but more informative graphs. Based on given user ID, the program will load graphs of that user into user graph set if program can find user emotion data of this user. Otherwise, only the default graph set will be loaded.

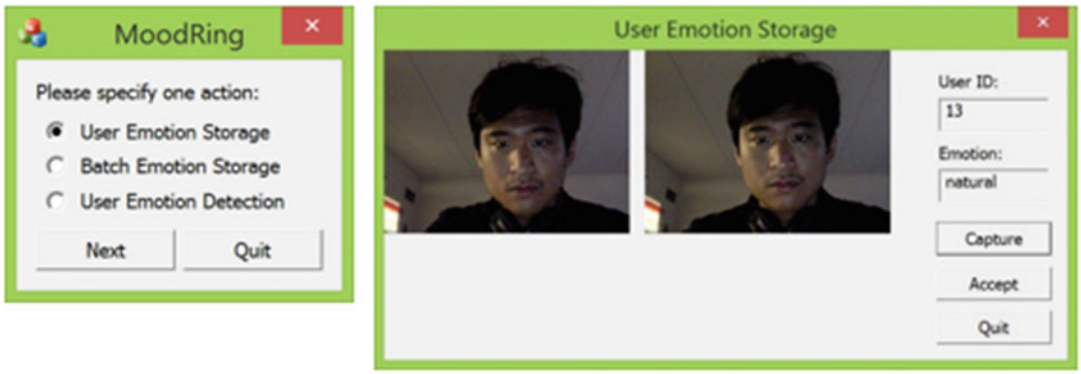
Weight Trainer

Weight Trainer is the first step to set up the MoodRing system. Input of this module is a set of elastic bunching graphs with all seven emotions; output is a weight matrix stored as local file.

Given a set of seven graphs, G_i (i = 0, 1, 2, 3, 4, 5, or 6), and each graph G_i has subgraphs g_{ij}, we first generate the dataset through a pairwise comparison:

$$\begin{aligned} x &= g_{ij} - g_{mn}, y \\ &= \begin{cases} 0, & \text{if } i = m \text{ (same emotion)} \\ 1, & \text{if } i \neq m \text{ (different emotion)} \end{cases} \end{aligned}$$

Then, because y is between 0 and 1, we apply the following logistic function on X:



Facial Recognition and Emotion Detection in Environmental Installation and Social Media Applications, Fig. 9 Training if the EmotionDetector

$$\text{Input matrix}: g(\mathrm{X}), \text{where x} \subset \mathrm{X}, \text{and} g(\mathrm{x}) = \frac{1}{1+e^{-t}}$$

$$\text{Output matrix}: Y, \text{where} y \subset Y,$$

Now that we have transferred the dataset into this form, we adopt certain classification methods, like LibSVM (Bolme 2003) to train the weight matrix. If size of X is small (e.g., for individual users), we will use batch training; if size of X is large (e.g., for the default user), we will use mini-batch stochastic training instead. The boundary of these algorithms is a constant value. Boundary p″ in this case means:

> For given testing sample g_{ij} and dataset sample g_{mn}, we can calculate the estimated $\hat{y}$ value using the trained model. If $\hat{y} \geq p$, we can conclude g_{ij} and g_{mn} are the same emotion type; otherwise, they are different.

Future Work

- Application of the detection is feasible in installation and environments, and public spaces.
- Further experimentation is necessary to determine accuracy of the facial capture and emotion detection.
- Further work will include continued refinement of the image processing and normalization to operate in varying lighting conditions.
- Mobile app and social media application exploration will continue.
- Experimentation and comparison of image library-based implementations and EBGM for the further development of a "universal" detector.

Fall Risk Detection in Computer Vision

Yen-Hung Liu and Patrick C. K. Hung
Faculty of Business and IT, Ontario Tech University, Oshawa, ON, Canada

Synonyms

Anomaly detection; Computer vision; Fall risks; Machine learning; Pose estimation

Definition

Anomaly Detection
Anomaly detection identifies unexpected items or events in data sets from the norm.

Fall Risks
Fall risks are common threats affecting all individuals, including the elderly or young children.

Computer Vision
Computer vision is an Artificial Intelligence (AI) system incorporated with other scientific fields, such as signal processing and neurobiology, to interpret and gain a high-level understanding of digital images or videos.

Machine Learning
Machine learning employs software tools from advanced analytics that use statistical algorithms to find patterns in datasets. Machine learning algorithms have two categories: (1) Supervised learning: The data is labeled and trained according to various classes, such as malicious and legitimate, to form mathematical models for the algorithms. Next, (2) unsupervised learning: The data is not labeled or trained. However, the algorithms determine the degree of data coherence to create classes according to the quality of data coherence within the classes and data modularity between them.

Pose Estimation
Pose estimation is a computer vision technique used for identifying human postures.

Motivation and Background

Fall risk is a common occurrence threatening individuals of all ages, from young to older adults. Typically, older adults are at a higher risk of falling. Poor eyesight, poor balance, and medication that causes drowsiness can cause severe harm and danger. Researchers continuously investigate evidence-based strategies to prevent falls, examine contributing factors like human behavior, and implement advanced technologies to monitor an individual's balance and movement.

Related Works

Previous studies on fall detection can be classified into two main groups: vision-based and sensor-based methods.

Sensor-based methods can be further divided into wearable-based and ambient fusion-based methods. Wearable-based methods mostly employ accelerometers and gyroscopes, and combining multiple sensors can improve their accuracy (Wu et al. 2012). In contrast, ambient fusion-based methods require various sensors, such as vibration, acoustic, pressure, infrared, Doppler, and a near-electric field, to detect falls. To identify fall occurrences, Werner et al. (2011) studied the vibration generated by a fall event from an Activity of Daily Living (ADL) event. However, this approach's high false alarm rate is a significant drawback.

On the other hand, vision-based methods can be categorized into two types: Red, Green, and Blue (RGB) images and depth images. Kinect is a commonly used equipment for extracting depth information in images; where used it to obtain a human bounding box, and used it to extract a human skeleton. Machine learning techniques such as Support Vector Machines (SVMs) were applied to identify fall events based on these features. However, Kinect has limitations when it comes to sunlight and outdoor environments. Convolutional Neural Network (CNN) has emerged as a game changer for RGB images. Lu and Chu (2018) used an object detection model (YOLO V3) that considers the relationship with the surrounding object to design their fall detection system. However, the performance of this approach heavily relies on camera angles, leading to the development of the pose estimation approach. The pose estimation method, OpenPose, can identify human skeletons and postures, leading to better identification of human motions used OpenPose to identify unstable centers of gravity during a fall event to detect fall events more accurately.

Structure of the Learning System

In general, older adults are at high risk of this injury due to changes in their body frame, physical and mental health, and cognitive alterations. In addition, fall risk depends on the individual, their physical environment, and their lifestyle. However, children and other individuals can also be prime victims. Falls are severe, but computer vision technology can detect them. In addition, fear of falling is an issue that individuals are prone to feel after their fall incident (Araya and Iriarte 2021). Many studies show different assessment methods and evidence-based approaches to deliver accurate data regarding fall risk causes and prevention methods.

Synonyms

MMORPG; Multiplayer game; Action adventure game

Definition

MMORPG = Massive Multiplayer Online Role-Playing Game is a multiplayer game designed to be played online

Multiplayer Game = a game that is designed for multiplayer mode where two or more players are expected throughout the entire gameplay

Action Adventure Game = a game that combines core elements from both action game and adventure game genres

Introduction

Final Fantasy 14 Online is an MMORPG developed by Square-Enix and published for the PC and PlayStation markets. It is popular to the point that they had to lock down the free-trial and stopped selling digital copies for a few months in order to keep the player countdown as to not overload the servers with the expected launch of "Endwalker," the latest expansion to come down the pipeline.

Gameplay

Players create a Warrior of Light to play through the game. With a focus on role-playing, each player takes the helm of one of the major Scions

or outside characters like Gaius. Featuring a variety of classes and various activities, there are many ways to approach the game including smithing, adventuring, buying houses, and raiding.

With 19 "combat" classes split between four tanks, four healers, and 11 "DPS," there is a wide variety of playstyles to choose from. From close-range physical DPS to long-range magical, healing, or tanking, you can truly be the "Warrior of Light" that you have always dreamed about in a huge fantasy game. Along with this, there are also 11 classes dedicated to crafting and gathering, allowing you to make your own gears and collect your own materials. Not only can you run dungeons or take on fantastic bosses, you can spend hundreds of hours crafting your own gears and playing the in-game markets to make "Gil" and buy wondrous prizes.

Tanks: Paladin, Warrior, Dark Knight, and Gunbreaker (tvtropes.org 2022)

The primary style of play for tanks includes gathering "aggro" through the use of enmity-generating attacks and a "tank-stance" that increases the amount gained per strike, along with damage mitigation and a few debuffs that can be applied to enemies. Each of the tanks has a different playstyle: Paladin and Warrior are the safest whereas Dark Knight and Gunbreaker are the risky options. Gunbreaker is a favorite for some gamers due to the high DPS combos along with the extremely precise barrier abilities. Figure 1 is an image of a game character as a Gunbreaker.

DPS: Monk, Dragoon, Ninja, Samurai, Reaper, Bard, Machinist, Dancer, Black Mage, Summoner, Red Mage, and Blue Mage

Physical DPS, Ranged DPS, and Magical DPS classes play quite differently from one another, and they often have wildly different abilities. For example, Summoner and Red Mage both possess the ability to resurrect other players, which often comes in handy during raids and major fights. Ninja is famous for its high burst potential, but many players prefer more consistent DPS output from classes like Samurai or Reaper. The king of

Fantasy XVI Online, a Massively Multiplayer Online Role-Playing Game, Fig. 1 A game character as a Gunbreaker wielding the newest Relic weapon

all of these is Black Mage, having been the undisputed lead of all DPS since the game's inception at a cost of limited mobility. Another favorite DPS is Reaper due to its high damage output and maneuverability, allowing it to zip around the battlefield and top the aggro chart with ease (see Fig. 2).

Healers: White Mage, Scholar, Astrologian, and Sage

Healers in this game are divided into two categories by the community: "Regen" Healers such as White mage and Astrologian, and "Shield" Healers like Sage and Scholar. Interestingly, the Astrologian straddles a line between the two categories given its abilities. While Regen healers focus on getting everyone to max health quickly with strong heals, Shield healers' main mechanic is to place shields on teammates in order to prevent major damage from taking place. One of the favorite healers is Sage due to the strong shield and its flexible cooldowns (see Fig. 3).

Reception

Originally facing lukewarm reception, each expansion of the game has received more rave reviews, culminating in being named one of the best MMOs of the generation. Many thought the hype surrounding the game had died with the culmination of the ShadowBringers storyline, with no one believing the following expansion would be able to top it. But the Endwalker expansion was not only considered a worthy addition, but it is now also being upheld as the bar of excellence in the MMO world. The game has achieved more credibility among even casual gamers, bringing another wave of new participants to the world of Eorzea. It was certainly helped by a generous free-trial offer that began around the initial outbreak of COVID pandemic. The free trial allowed users to play the original "A Realm Reborn" storyline as well as the hugely popular "Heavensward" expansion with two additional races and three extra jobs (Bussel 2022).

Fantasy XVI Online, a Massively Multiplayer Online Role-Playing Game, Fig. 2 A Reaper holding one of the new Major Relic Weapons

Fantasy XVI Online, a Massively Multiplayer Online Role-Playing Game, Fig. 3 A favorite Sage healer, not wielding a Major Relic Weapon

Tournaments

The game features a robust raiding community dedicated to "savages" and "ultimate" content that exist solely to challenge themselves to "races," that is, to be the first player to complete the new content as soon as it drops (mogtalk.org 2022). In addition, there was an official tournament in July 2022 for the game focused on the Crystalline Conflict mode that was region locked to Europe (Png 2022). In fact, one of the major game developers known as "Yoshi-P" can be regularly found participating in the PVP modes and fighting in Crystalline Conflict in order to personally test the competitive modes for the game and further improve it.

Conclusion

Final Fantasy XVI Online (FFXVI or FF-14) has become one of the best-selling MMOs, even surpassing internal sales metrics. The game experienced a huge boom of players during COVID-19, to the point that they had to stop offering the free trial and temporarily restrict people from purchasing the game in order to reduce the heavy load on their servers (Teixeira 2021). It has a large community that is generally positive and welcoming to outsiders. The community even offered a warm welcome to gamers who fled World of Warcraft when the controversies surrounding Blizzard came out. With continuously growing numbers, it cannot be denied that Final Fantasy XVI Online has become one of the biggest Massively Multiplayer Online Games in the world.

Definition

One of the most popular forms of biometrics used for personal identification is fingerprints. The extraction of multi-features illustrates the diversity of data represented from fingerprint samples, allowing mitigation of the intrapersonal variable. This study uses multiple feature extraction based on statistical tests of co-occurrence matrices to overcome the drawbacks of previous methods and minutiae extraction to achieve high accuracy toward an efficient fingerprint verification system.

Introduction

The most important type of human biometrics is fingerprints. Fingerprints have been used for personal recognition in forensic applications, such as criminal investigation tools, national identity card validation, and authentication processors. The uniqueness and immutability of fingerprint patterns as well as the low cost of associated biometric equipment make fingerprints more desirable than the other types of biometrics (Maltoni and Cappelli 2009). A characteristic attribute of false fingerprints in the large view of complexly refers to forgery, combined with the actuality that

fingerprint samples are distinctive to each individual. In reality, fingerprints present a distinguished basis of entropy that is used for security implementations (Dodis et al. 2006; Dass and Jain 2007; Khan 2009). There are two classes of features utilized for the recognition system: global attributes and local attributes (Ebrahim 2017a). The global attribute pattern represents a distinctive modality of a singular point as the center point that is utilized for fingerprint recognition. The local feature represented from fingerprint's ridges data is called minutiae. The fingerprint verification (FV) system includes three processes: the fingerprint obtaining apparatus, extracted features, and verify features (Igaki et al. 1992). The dataset of FVC2002 is utilized to obtain the finger imprint by an optical device, which has high capability (Maio and Maltoni 1997). The extracted minutiae and minutiae verification are further obtained in the next stage.

A fingerprint authentication scheme is a model matching scheme that distinguishes the individual based on their fingerprint attribute (Maltoni et al. 2003). A number of various fingerprint classification systems have been improved using myriad classification approaches and datasets. Each classification method has its own specific characteristics that researchers capitalize on to advance fingerprint classification research using a particular dataset (Jain et al. 1997; Jea and Govindaraju 2005). In order to design a more reliable automatic identification system, preprocessing of fingerprints has to take place to enhance and extract fingerprint features (Wu et al. 2006; Rajkumar and Hemachandran 2011). According to Maltoni et al. (2009), most current fingerprint classification approaches depend on global attributes, including ridge orientation areas and singularities. Bazen and Gerez (2002) found that accurate classification of fingerprints is highly dependent on the orientation fields' estimation and singular points detection algorithms. Later, Arivazhagan et al. (2007) suggested a fingerprint verification system utilizing Gabor wavelets. Yazdi and Gheysari (2008) utilized co-occurrence matrices to verify the fingerprint image.

Preprocessing Fingerprint Enhancement

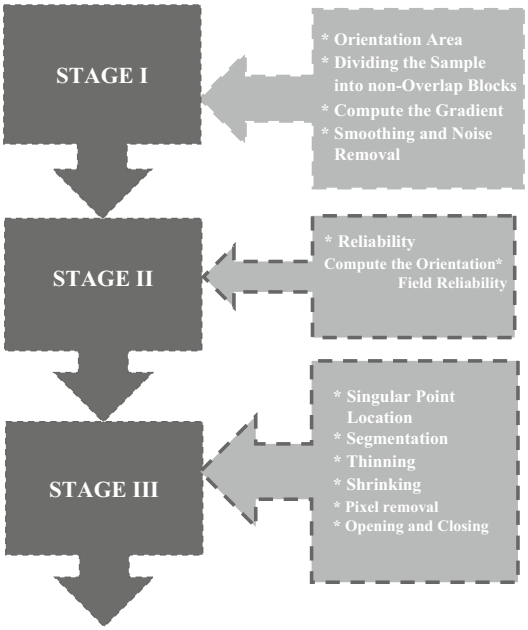
Image improvement of fingerprint samples is very important for FV to function correctly. The efficiency of the image of the imprint sample is influenced by noise in ridges produced by the under-inked region, varying the fingerprint attributes because of skin elasticity, where splits are from dry skin and wounds may cause ridge discontinuities. To preserve the high accuracy of the FV system, two procedures utilized in the unique mark recognition basis (STFT) analysis suggested by Chikkerur et al. (2007) are utilized here for image enhancement of fingerprints and procedures. The system can be shortened as follows: The image of the fingerprint is split into overlapping squares. Then STFT analysis is performed. The test productions are images of ridge orientation O(x,y) and ridge hesitation F(x,y). The next stage O(x,y) image represents smoothing of the orientation. For improvement, each overlapping square B(x,y) in the image has been rebuilt for the sample by creating improved blocks $B^0(x,y)$.

Feature Extraction Methods

The fingerprint sample illustrates a scheme of oriented texture and contains important data. This scheme utilizes an ensemble of dichotomizes to combine features through several measures and feature extraction methods, commanding lower cost and accurate FV. The approach utilizes multi-feature extraction at different measure techniques for classification of preexisting extracted feature systems, creating a large set of features (Ebrahim 2017b; Ebrahim and Sulong 2014). The performance of fingerprint images is realized by applying two methods based on singular point detection and fingerprint ridge thinning, as discussed in the next section.

Singular Point Detection Technique

The image of a fingerprint is made up of the design of ridges and valleys that is a copy of the individual imprints. The reference point is the point with extreme curvature on the convex ridge, and to define the single reference point reliably for all varieties of fingerprint samples, the orientation area, which characterizes the



Fingerprint Verification Based on Combining Minutiae Extraction and Statistical Features, Fig. 1 Singular point block method diagram (Kaas and Witkin 1987)

local orientations along the prevalent orientation, is utilized to distinguish the reference point. The reliability can also be calculated applying the method projected by (Ebrahim 2017a) and (Kaas and Witkin 1987). Figure 1 shows the block design for detecting the singular point and the implementation.

Orientation Area

The first stage of finding the singular point is computing the orientation area. The orientation field is critical for the computation of the reliability. The accuracy of the reliability robustly depends on the accuracy of the orientation area values calculated. Below are the steps for orientation calculation:

The fingerprint sample is split into a non-overlapping block of size (W × W). In this paper, W is set to 16.

The horizontal and vertical gradients $G_x(x, y)$ and $G_y(x, y)$ at each pixel (x,y) respectively are calculated applying simple gradient factors (Gonzalez and Woods 2008).

The ridge orientation of each pixel (x,y) within a W × W window at points [xi,yj] is calculated as follows (Ratha et al. 1995):

$$\theta(x.y) = \frac{1}{2}\tan^{-1}\frac{2G_{\mathrm{xy}}}{G_{\mathrm{yy}-G_{\mathrm{yy}}}}. \tag{1}$$

Because of noise, an inclined ridge, valley structures, and poor gray value, a low-pass filter can be applied to regulate the incorrect local ridge orientation. However, to achieve the low-pass filtering, the orientation image must be transformed into a continuous vector area, and the Gaussian low-pass filter can be used as follows:

$$\Phi_y(x.y) = \begin{array}{l}\sum_{u=-1}^{1}\sum_{v=-1}^{1} l(u.v) \\ \times\Phi_y(x-ul.y-vl)\end{array} \tag{2}$$

where l is a 2-directional low-pass filter with a complete unit.

The orientation area can be representing in this section.

Reliability

Meanwhile the singular point has the maximum curvature. It can be found by calculating the strength of the reliability peak applying the following equation:

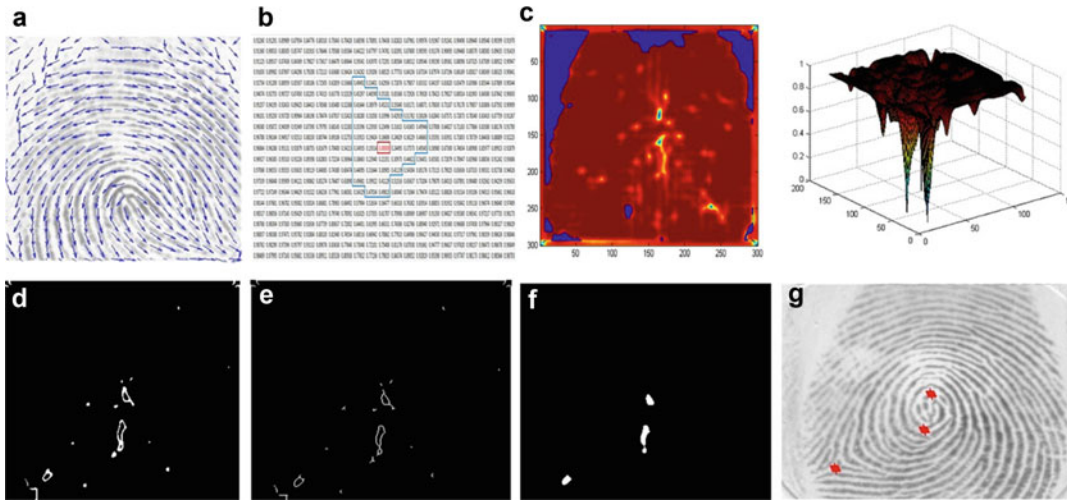
$$Y = 1 - \frac{Y_{\min}}{Y_{\min}}. \tag{3}$$

Figure 2 displays the orientation area reliability and the singular point value in the center. The reliability rate of the singular point is $= 0$, but the value of background is also zero. However, there is a contour around the singular point of the reliability value of the contour between < 0.5 and > 0, and this is the area of interest.

Singular Point Location

After calculating the orientation area reliability, the next stage is to detect the singular point place. This can be achieved by the following stages:

F



Fingerprint Verification Based on Combining Minutiae Extraction and Statistical Features, Fig. 2 The detecting of singular point by (**a**) Orientation field on original fingerprint, (**b**) Both singular point and orientation field reliability within the contour, (**c**) Reliability image map to three singular points, (**d**) Region of interest after the segmentation, (**e**) Singular point contour after thinning, (**f**) Filled singular point contour, (**g**) Singular point location on the original fingerprint

(i) The orientation field reliability needs to be segmented into two distinct regions. The region of interest contains the values > 0 and < 0.5.

The result of the segmentation can be seen in Fig. 2.

(ii) Thinning is the process of adjusting the width of contents of the image to one pixel while preserving the extent and connectivity of the original shape.

(iii) After thinning, all pixels will be removed so that the contour shrinks to a connected ring halfway between each hole and the outer boundary, and the rest will shrink to a pixel that will be removed. Figure 2 shows the singular point contour without any noise.

(iv) The singular point contour is well defined, and to determine the location of the singular point, the contour is filled using the morphological hole filling equation (Gonzalez and Woods 2008):

$$F\ (\mathrm{x.y}) = \begin{cases} 1-I(x.y) \\ 0 \end{cases}, \qquad (4)$$

where "(x, y)" represents the border of I; otherwise, H is equal to the input image I, with holes filled.

(v) Here, the singular point pixel can be found by performing the shrinking process for the singular point contour. Figure 2 shows the singular point pixel after applying the shrinking method, the position of the singular point on the original fingerprint, and Singular point pixel.

Fingerprint Thinning Minutiae Marking

Thinning is a procedure by which the sizes of the ridges are reduced. In each scan of the full imprint image of a fingerprint, every sample square represents (16 × 16) pixels (Maio and Maltoni 1997). This image along with other data will be recorded into the dataset (Jain et al. 1999). After obtaining this input file, it will undergo binarization. Usually, a vision of the distinctive mark will be obtained.

Normalization

Normalization is a procedure for fingerprint verification. Samples of fingerprints do not come in the same dimensions. Because of this, the samples need to be aligned suitably to confirm an overlap of the common area in the two samples of imprint by the orientation of the image to zero at the

reference point (Gonzalez and Woods 2008). Once all the features of each fragment have been extracted, then the feature values are normalized in the interval [0 1]. Normalization of features is very important because if the values of different features are in different ranges then the higher values dominate the lower values. Thus, the normalization technique makes the feature values in the same scales and ranges. The image of the fingerprint is split into a non-overlapping set of size W × W (for each 16 × 16) and the orientation that matches the most controlling orientation of the block (Ebrahim et al. 2018; Ebrahim and Ashoor 2018; Ebrahim 2018). After the process, the features of ridges in the fingerprint are represented in black and furrows are represented in white.

Multi-feature Extraction

There is a pressing need to develop a fingerprint verification system with software-based minutiae extraction and statistical features. The proposed approach is to extract the most suitable multi-features for classification. In this study, we combine a set of the strongest features. The effectiveness of the projected method has been evaluated through a comparison with several existing techniques for multi-features.

Tests have been executed depending on standard datasets. However, more accuracy lowers the popularization capabilities. In fact, the background minutiae extraction and statistical features have already managed to detect the differences in fingerprints, and statistical attributes are utilized by other FV systems, for example (Yazdi and Gheysari 2008). In this research, multi-features are extracted from different parts of the fingerprint, therefore increasing its selective power. There are also many outliers in each class, which are circled. The outlier is an observation that carries an irregular distance from its neighboring feature values that will result in misclassifications. Hence, it is observed that minutiae extraction or statistical features alone inherit some weaknesses, such as overlapping and outliers, which reduce their discriminating abilities.

Fingerprint Verification

Matching is an important part of fingerprint verification. It compares two features and returns a likeness score to indicate how comparable the two participating fingerprints are. The comparison depends on discovery of the Euclidean distance between the attribute of the conforming fingerprints.

The EER for experiment was computed by the FVC2002. In Table 1, the databases were split into four databases: DB1, DB2, DB3, and DB4. Each dataset contains 800 fingerprint samples collected from 100 persons, and each one is eight impressions. Sets of tests were carried out for each database, and the protocol is shown in Table 1. Yang et al. (Yang and Park 2008) used the tessellated invariant moment feature, Ross et al. (2003) used minutiae and ridge map features, Jin et al. (2004) used integrated wavelet and Fourier–Mellin invariant framework with four multiple training WFMT features, Amornraksa et al. (Amornraksa and Tachaphetpiboon 2006) used the DCT feature, Khalil et al. (2010) used statistical descriptors, and Flores et al. (2017) used Delaunay triangulations.

Conclusions

Low-accuracy fingerprint images require multi-features to expand distinction. The process for

Fingerprint Verification Based on Combining Minutiae Extraction and Statistical Features, Table 1 EER (%) evaluation of the current techniques

Technique	DB1	DB2	DB3	DB4	EER
Yang et al. (2008)	1.63	3.78	4.20	4.68	3.57
Ross et al. (2003)	1.87	3.98	4.64	6.21	4.17
Jin et al. (2004)	2.43	4.41	5.18	6.62	4.66
Amornraksa et al. (2006)	2.9	5.4	6.7	7.5	5.68
Khalil et al. (2010)	0.31	0.26	0.34	0.20	0.28
Flores et al. (2017)	0.125	0.125	0.75	0.75	0.44

FV comprises five sections: singular point detections, fingerprint ridge thinning, normalization, multi-feature extraction, and fingerprint verification. Moreover, minutiae extraction and the four statistical descriptors characterize the fingerprint texture. Each process plays an important role in fingerprint verification. Hence, to facilitate the accomplishment of such ambitious goals in the near future, researchers ought to perform statistical tests and minutiae extraction of fingerprint textures.

Definitions

Fire Emblem Fates released on June 25, 2015 in Japan and in 2016 in other regions for the Nintendo 3DS system. *Fire Emblem* is a tactical role-playing series that debuted on the Famicom with *Fire Emblem: Shadow Dragon and the Blade of Light* in 1990. *Fates* has three routes to play: *Birthright, Conquest,* and *Revelations*. This article will explain the background of *Fates* and what makes *Conquest* unique.

Introduction

Fire Emblem Fates is the fourteenth installment in the *Fire Emblem* franchise. *Fates* is split up into three different routes that have different game designs but share the same engine and mechanics. *Birthright* is designed to be similar to *Fire Emblem: Awakening,* the previous entry in the franchise. *Conquest* is designed for series veterans and those who seek a challenge. The *Revelations* route was added after launch with sandbox elements to allow players to have characters interact with other characters from the previous campaigns that may have not previously (Yamoto n.d.).

Unlike many strategy games of the time, *Fire Emblem: Shadow Dragon and the Blade of Light* differentiated units by giving them unique dialogue and personalities (Harris 2009). While the text was very barebones in *Shadow Dragon and the Blade of Light*, further entries in the series added a support system where units can talk to each other. After a certain point, units that support each other will assist each other in combat by increasing stats in combat.

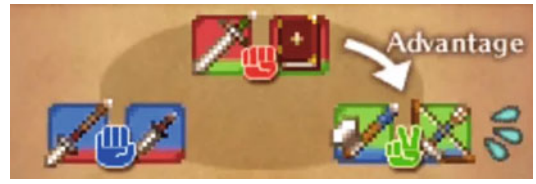
Fire Emblem Gameplay

Fire Emblem gameplay consists of moving units across a grid-based map to complete objectives, engage in combat, and manage character stats. Map objectives usually include seizing castles, defeating bosses, or defeating all enemies. Units in the player's army are differentiated by starting stats, the rate that stats grow (often called growth rates), how well they can wield a weapon, and class. A unit's class determines their movement type, growth rate modifiers, and weapons they can wield. The four movement types are infantry, armored, cavalry, and flying. Infantry units can be thought of as the basic movement level. Armor units have lower movement but have more defensive stats. Cavalry units can move more spaces but are slowed down by terrain, such as forests and hills. Flying units can move across any terrain with ease but are weak to arrows among other things. After a class has collected enough experience by performing actions, they can be promoted to a higher-ranking class, giving them more stats and weapons to wield. Common unit stats that are in many *Fire Emblem* games are Health Points (HP), Attack, Defense, Magic, Resistance, Speed, Skill, and Luck. Once a unit's HP reaches zero, they die. Attack is how much damage a unit can do in combat. Defense is used to reduce damage from an attack. Magic is used to calculate damage with tomes and other magical weapons. Resistance reduces damage from magical attacks. Speed affects a unit's dodge rate and

gives units the ability to perform a follow-up attack (often called doubling) if they reach a certain threshold of speed difference with an opponent. Skill is used to calculate how accurate attacks are and can be used to activate skills. Luck is used to manage the rate of critical hits, evasion, hit, and skill activation. A common mechanic that exists in many *Fire Emblem* games is the Weapon Triangle, where sword units have an advantage against axe units, axe units have an advantage against lance units, and lance units have an advantage against sword units. Other typical weapons are magic tomes, staves, and stones that allow their units to transform in battle. In most *Fire Emblem* games, weapons have durability that the player needs to keep in mind as to not be left defenseless. In most *Fire Emblem* games, when a unit falls in combat they are considered dead and will not participate in the story.

Fire Emblem Fates Gameplay

During the development of *Fire Emblem: Awakening*, it was internally planned to be the entry in the series if it did not sell well (Kantopia 2021). After *Awakening* sold very well, Intelligent System hoped to recreate what made it so popular while addressing mechanical criticisms. *Fire Emblem Fates* tells the story of Corrin, a noble born to Eastern-inspired nation of Hoshido but raised in the Western-inspired nation of Nohr. Nohr and Hoshido are on the brink of war when the game begins. Corrin must soon decide what nation to fight for. Fates made several changes to the weapon systems. Weapons no longer break and several have secondary effects, typically raising or lowering stats. Keeping with the themes of Western versus Eastern influences, each kingdom has slightly different weapons: swords/katanas, tomes/scrolls, axes/clubs, bows/yumi, lances/naginata, and daggers/shuriken. Hoshidan weapons are typically weaker when coming to raw strength while adding more stats in other areas, such as katana granting more speed while dropping defense and resistance. In addition, Nohrian staves have stranger healing capabilities than their Hoshidian counterparts, rods. However, rods can reach allies that are farther away. In addition, the weapon triangle has been updated to include all weapons, besides stones and monster classes (Fig. 1).



Fire Emblem Fates, Conquest, Fig. 1 The *Fates* weapon triangle

In *Awakening*, a mechanic called Pair Up allowed two units to occupy the same square with one leading and the other standing behind. The unit in the front will gain stats according to their partner's stats, class, and support level with the lead unit. They may also occasionally enter combat to perform extra hits or block enemy hits. This system was criticized by series veterans for being too overpowered and unstrategic as the bonuses were unreliable and unviewable. Enemies in *Awakening* are unable to use Pair Up. *Fates* responded to these criticisms by splitting Pair Up into Attack Stance and Guard Stance (Ramey 2020).

In Attack Stance, an adjacent ally will be able to join combat after the main unit has attacked with slightly less damage and the inability to perform a follow-up attack. In Fig. 2, Odin's damage, accuracy, and critical chance are in the left column while Ophelia's is in the middle column. The archer's statistics are in the right column.

In Guard Stance, two units can occupy two spaces. The lead unit will gain stats according to their partner's class, support ranking with the lead unit, and stats that each unit innately gives their support partners. In addition to stat gains, the pair gets a Guard Gauge. The Guard Gauge starts at zero shields and is full at ten shields. For every hit that the lead unit receives or deals, the shield raises by two. Once the Guard Gauge is full, the backing unit will jump in to fully block a hit from the lead unit. Units in Guard Stance cannot be hit by the foe's Attack Stance partner. If the units unpair or switch with other partners, the average Guard Gauge will average between the two

Fire Emblem Fates, Conquest, Fig. 2 Odin is attacking an enemy archer with assistance from Ophelia

Fire Emblem Fates, Conquest, Fig. 3 Keaton is paired up with Camilla in guard stance to attack an enemy Faceless

pairings. Enemy units can use both Attack and Guard Stance.

In Fig. 3, note the full Guard Gauge at the below the blue HP bar; Camilla will block the foe's next attack in combat.

Fates makes several changes to the class systems. Once again keeping with West versus East themes, many Nohrian and Hoshidan classes share characteristics. For example, the Nohrian class Outlaw can be seen as equivalent to the Hoshidan Ninja as they both are used to pick locks and are rather quick. There are also ways to reclass. Units can reclass into a stronger class starting at level 10. All units have a secondary class they can reclass to with a Heart Seal. Units can reclass into their married partner's class with a Marriage Seal. Units can reclass to the class that their best friend (units are best friends if they reach the highest level support rank, A+) has. Units will gain skills by leveling up in classes. Skills are buffs that can range from raw stats, more movement options, the ability to give stats to allies, more powerful attacks, etc. All main characters have personal skills that are innate and are exclusive to them.

If units gain a high enough support level, they can wed and have children. Children will be based on their father (Silas will always have Sophie as a child) while the mother will pass down their hair color. The opposite is true for Azura's child and Corrin's child, if Corrin is female. With the power of space-time travel, the children are able to be recruited into the player's army after beating their chapter. Child growth rates will change based on averages of their parents. Parents will also pass down their last equipped skill and their classes. Children can access these classes with a Heart Seal. If a child's chapter is done after chapter 18 of the main story, the unit will come with an Offspring Seal that allows them to gain access to a higher-level class with extra level and weapon rank that is curved to the enemies of the main chapter.

Units that have blood of the First Dragons can access Dragon Veins during battle. With them, players can change terrain, heal, or buff allies, damage or debuff allies, etc.. While Dragon Veins aren't usually necessary to a map's objective, they often provide more dynamic ways to strategize as each map has a unique effect.

At the start of the game, the player is able to customize their avatar, who's default name is Corrin. The player can customize their gender, voice, hair color, and accessorize them. The player can also choose their secondary class with their boons and banes. The boons determine what stats Corrin excels in by modifying growth rates. Likewise, the banes will determine what stats Corrin struggles with.

Between chapters, players will have access to My Castle. My Castle is a place where players can view supports, buy weapons and items, talk to other characters, forge weapons, and collect resources to customize the castle. My Castle serves as a downtime between chapters that allows players to plan out their next moves. Supports are built between characters as lines of conversation. Characters have up to three supports with their support partners, labeled C, B, and A. A fourth level of support is available to marriage candidates and best friends (S and A+, respectively). Forging weapons allow for weapons to become more powerful and for

players to name their weapons. Using the Mess Hall gives the chance to give slight buffs to allies for the next battle. The units Niles and Orochi have personal skills that allow them to capture certain enemy units. They can be recruited into the player's army at the Prison. Occasionally, players will be challenged to battles by mysterious forces and have to defend their castle. Players can also go online and visit castles that belong to other players and challenge them to battle.

The first five chapters of *Fates* are the same. In chapter six, the player can choose to send Corrin down the *Birthright*, *Conquest*, or *Revelations*. When selecting *Birthright*, the game gives the description of, "This path includes opportunities to freely accumulate experience points and gold. This will allow you to enjoy watching your characters grow faster." When selecting *Conquest*, the game gives the description of, "This path allows you to test your skills and devise complex strategies while progressing with limited access to experience points and gold." When selecting *Revelations*, the game gives the description of, "It is not recommended to select this path for your first playthrough. This route is best experienced after playing both the Defend Hoshido and Fight with Nohr paths."

Embrace the Dark

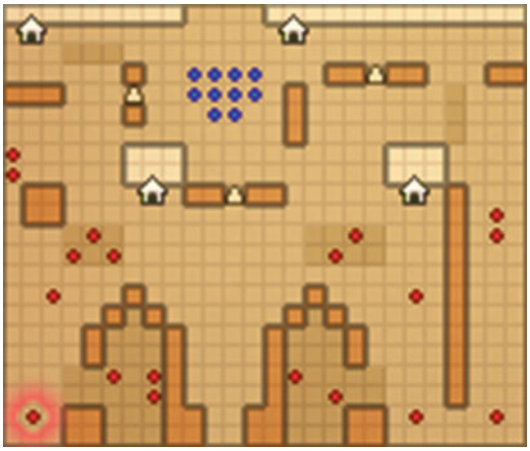
Conquest's "limited access to experience points and gold" changes the way players play the game. In the two other routes, players return to My Castle after every chapter. From there they can choose to scout on completed maps for extra enemies or choose side chapters provided they meet the conditions to unlock them. *Conquest's* limited maps force players to play tighter in the chapters they do have. *Conquest* players will have a harder time gaining supports between units, so experienced players will think about supports beforehand and dedicate some turns to building supports. On top of this, *Conquest's* maps are more difficult, having more varied objectives and side objectives. Enemy units have more skills, higher stats, and stronger artificial intelligence. Under most circumstances in *Conquest*, enemies will not engage in combat if they can do zero damage. In maps where the main objective is to have the player defend a point, enemies will sometimes refuse to fight the player and rush their objective. Enemies will also use Dragon Veins to their advantage. Another design difference from *Birthright* and *Revelations* is the lack of what the *Fire Emblem* community calls "ambush spawns." Ambush spawns are reinforcements that appear and take an action on the same turn. All of these factors work together to make *Conquest* more challenging and rewarding to players who can plan out complex strategies in advance.

Unhappy Reunion

The tenth chapter of *Conquest*, Unhappy Reunion, is thought by many *Fire Emblem* fans to be an example of a well-designed map. Many more believe that Unhappy Reunion is one of the hardest maps in the series. In chapter 10, Corrin is attempting to find a boat to transport their army to find the Rainbow Sage. To Corrin's surprise, the Hoshidian prince Takumi is sending an army to Nohr. Refusing to let Hoshidans on Nohrian soil, Corrin sets out to defend the port town.

In Fig. 4, blue tiles represent water tiles that only flying units can traverse, the darker tiles represent walls, and white tiles represent roofs. The northern section of the map is a boardwalk that has two houses. The middle of the boardwalk has a green section that Corrin must defend. If a unit visits them, the top left house will give ten thousand gold and the top right house gives a Master Seal. South of the gold house lies a breakable wall. To the left of the starting position is a Fire Orb, an item that mages can use. Next to the house that gives a Master Seal is a ballista. Another ballista can be found below the starting position. The house in the middle left gives a Dual Club, a weapon that reverses weapon triangle advantage and doubles its effects. The wall to the right of the house is breakable. The middle right house gives a defensive stat booster. At the southwest section of the map is Takumi holding an Elixir, an item that restores 99 HP. Takumi is standing over a Dragon Vein, but the game will not show its description. Behind the middle left section of units

Fire Emblem Fates, Conquest, Fig. 4 *Conquest* Chapter 10 Map



Fire Emblem Fates, Conquest, Fig. 5 Chapter 10 map with water drained

is Hinata, Takumi's retainer. Behind the middle right section of units is Oboro, Takumi's other retainer. At the southern part of the map are two boats with a Sky Knight flying between them. Ninja, Oni Savages, Archers, and Spear Masters will appear as reinforcements periodically on the left and right side of the map. More Sky Knights will appear from the South.

The opening position provides an advantageous position to defend the point: walls to the South and West, a Fire Orb, and Ballistae. On turn three, Camilla and her retainers appear, Beruka and Selena. Camilla is a Malig Knight, Beruka is a Wyvern Rider, and Selena is a Mercenary. Camilla and Beruka are flying units, so players will find the ability to cross water useful. On the fifth turn, reinforcements will start appearing and moving toward the green section (Fig. 5).

On turn seven, Takumi will activate his Dragon Vein, causing the water to drain from the map allowing all units to traverse them. All enemy units will then begin to rush their objective. Players who played defensively will find it hard or impossible to defend the objective without casualties due to the sheer number of units rushing at them.

Players who know about the reinforcements and Takumi using the Dragon Vein will tend to realize that playing defensively as the objective suggests isn't the best strategy. Trying to get out of the starting position to chip away at the enemy numbers before they rush toward the point will greatly help. Clearing out units near the middle houses early will give the players the ability to visit them, although it is not required. Due to the complexity of this map, Veteran players of *Conquest* will plan their playthrough around this chapter. Camilla and Beruka are very helpful as units due to their flying mounts. Being flying units, they are able to quickly traverse the map. Using heart seals, some players change their units' classes to have greater movement for this chapter. Elise and Corrin (if they picked Wyvern or Sky Knight as their secondary class) can reclass into flying classes. Jakob has the ability to reclass into a Paladin for cavalry movement. Buying weapons that have one and two range attacks will give the ability to counterattack the ninja. Breaking the wall next to the house containing the Dual Club will allow for the ability to exit the starting position and challenge Hinata faster. Camilla is one of three units by default that can wield clubs, so most players will give it to her if they chose to fight Hinata. Purchasing the Nosferatu tome for Odin will give him the ability to leech life from enemies. With this, Odin is able to challenge several units without requiring a staff unit to be nearby. Once Takumi drains the water, some players will try to congregate near the starting position to form a wall and challenge the remaining units. Camilla, Beruka, and any other high movement units are able to chase down the enemy flying units. If the fliers get too close, bow units will make quick work of them.

Unhappy Reunion's complexity, rewards, side objectives, and the ability to challenge the map in many different ways give players a sense of accomplishment when beating the chapter.

Eternal Stairway

The 21st chapter of *Conquest*, Eternal Stairway, is another map that is lauded by many that play as a map that tests players' knowledge by flipping traditional mechanics on their head. In Eternal Stairway, Corrin's army is invading Hoshido and is using an alternate route through the Wind Tribe lands to sneak around the main Hoshidian army. As they are traversing the Eternal Stairway, they are suddenly surrounded by monsters called Faceless and Stoneborns. The monsters are too vast in numbers to fight them all so Corrin and their allies are forced to find a way to escape.

Chapter 21's objective is "Escape with all units." All units must make their way from the starting area located at the bottom of the map through several large steps to the top of the map to escape. On the steps are Dragon Veins that will reduce all foe movement to zero. Scattered across the stairway are Faceless and Stoneborn. Faceless are one ranged enemies that come equipped with the Savage Blow skill, which reads, "When user triggers the battle, enemies within a 2 tile radius have their HP reduced by 20% after the battle." On harder difficulties they have skills that reduce accuracy for a specific weapon type. Stoneborn are enemies that launch stones at their foes from up to five tiles away. They come equipped with Wary Fighter, a skill that prevents enemies from making follow-up attacks. On harder difficulties, they come equipped with Renewal, a skill that lets them regain 30% of their HP at the start of the turn, and Heartseaker, a skill that reduces foes avoid. At the top of the staircase is a boss Faceless that holds an Arms Scroll, an item used to increase weapon rank. Additional enemies will endlessly appear at the top and bottom of the map. They come equipped with Wary Fighter, Grisly Wound (a skill that reduces enemy HP by 20% after battle), and Void Curse (a skill that prevents experience gain) (Fig. 6).

Fire Emblem Fates, Conquest, Fig. 6 Chapter 21's map

When tasked with a chapter that has a different objective, players will be forced to adapt their playstyle. One solution to clear the map quickly is to undeploy everyone except Corrin and a flying unit that can use Dragon Veins. They will then pair up and activate every Dragon Vein as they fly over the steps toward the end. While this is a valid strategy, players will miss experience gained by defeating enemies. Players have several options to maneuver up the stairway. In much the same way that chapter 10 forces players to defeat enemies early before they can swarm, Eternal Stairway forces players to defeat foes as they climb the stairway or fight the endless waves of monsters. Flying units have movement advantages as they can fly over the steps and easily access the Dragon Veins that are needed to freeze the monsters to keep the other units safe. Armored units are paired up with other units with more movement or have their class changed entirely as to not lag behind. Infantry and other mounted units can clear the Faceless on the sides of the stairs to make a path for units that can't take many hits from the Faceless and Stoneborn. In order to dispatch units with Wary Fighter, some players use blessed weapons, a class of weapons that deals extra damage to monsters. Other players use brave weapons. Brave weapons are a class of weapon that lets their wielders attack twice consecutively when initiating combat but makes them lose five speed. Brave weapons are usable at A rank so only units that have invested lots of time into a

specific weapon can use them. The Lightning tome is a brave tome that can be used a C rank instead of the usual A. Attacking the Stoneborn in Attack Stance will allow players to hit them four times in a round of combat if both attackers are using brave weapons.

Eternal Staircase is a map that flips traditional Fire Emblem game mechanics on their head in ways that force players to design new strategies using the units and resources they already have.

Conclusion and Discussion

Fire Emblem Fates: Conquest is a game that was designed for fans of strategy games, *Fire Emblem* veterans, and those who seek a challenge. *Conquest* rewards players who can analyze the problems thrown at them and plan out their moves in advance. The new mechanics of Attack Stance and Guard Stance allow for players to perform more complex strategies that previous entries did not allow for. *Conquest's* experience is crafted in a way that allows for player experimentation while also retaining its difficulty.

Definition

First Person Shooter	A type of game play mode that lets the user (gamer) see the character they are playing.

FPS	First Person Shooter.
Maze War	A simple 2D maze type of FPS.
Wolfenstein 3D	A 3D version of Wolfenstein that came out 1981.
DOOM	The first true 3D game that came out in 1993, which launched what we now know of FPS.
Quake	A 3D game that took what DOOM made and made it better; it was also one of the first Esports games.
Duke Nukem	An FPS game that gives the main character more of the starlight with lines than he would use during game play.
Unreal	A 3D FPS game engine.
Unreal Tournament	A multiplayer game with area-based "deathmatches."
Deathmatch	A genre of multiplayer video game in which a player's goal is to kill or eliminate the opponent from the match.

First Person Shooter (FPS) Games

The first First Person Shooter (FPS) game came out in 1973. It was known as "Maze War." The game was created by Steve Colley, Greg Thompson, and Howard Palmer; it was playable over ARPANET between multiple universities (Jensen 2017).

The true FPS games arrived in the 1990s when 3D graphics took off and 3D game engines became available. Wolfenstein 3D (developed by id Software and published by Apogee Software and FormGen) came out in 1992. It was the first stepping stone for all FPS to date. The game was created by employees at iD software: John Carmack, John Romero, Tom Hall, and Adrian Carmack. These same people made the next FPS called "DOOM" that are still being used today to help create new FPS games (Coldewey 2013).

In 1996, another FPS game took 3D graphics farther by letting the player choose the 3rd person mode, as well as giving the character a voice. The game was called "Quake" that uses iD tech engine – the first game engine. Quake, published by GT Interactive, would become one of the first e-sports game that offered the winner a prize.

Some FPS games such as "Call of Duty" use real world events. "Call of Duty," published by Activision, would take the gamer to the beaches of Normandy, and all the way to future warfare that has yet to be seen. Activision came out with the game in 2003 for PC, adding different campaigns for different countries and the way they fought in each war. The game used iD tech engine.

The game "Duke Nukem" gave the playable character an icon for wisecrack speeches during gameplay. Scott Miller of 3D Realms created the game and sold the rights to Gearbox Software in 2010. Gearbox later released "Duke Nukem Forever" with higher quality graphics.

Unreal Engine

FPS would go even farther with better game engines (Buckley 2022). The second game engine was called "Unreal" which came from the company Epic Games. FPS games created using the first version of the Unreal engine include "Star Trek: Next Generation: Klingon Honor Guard" and an adaptation of Robert Jordan's "Wheel of Time" series. But the most memorable game was "Unreal Tournament" by Epic Games in 1999. "Unreal Tournament" was a multiplayer game with area-based "deathmatches." A deathmatch is a genre of multiplayer video game in which a player's goal is to kill or eliminate the opponent from the match.

The game that took everything known for FPS and rewrote it was "Halo: Combat Evolved" in 1999. Bungie made "Halo" into the largest game-based FPS ever. The game used artificial intelligence that would learn from the gamer and would make the gameplay harder at each level. It had different multiplayer modes, both online and offline. The game publisher Microsoft Game Studios later gave "Halo" to 343 Industries, which continued to make the franchise game.

FPS started out as a basic 2D type of maze game, and it evolved to a 3D Real Time-based strategy game – games where hearing and

speaking can either help you or hurt you in the gameplay – which added a new dimension of realism.

Virtual Reality

Virtual reality (VR) gave FPS yet another dimension of realism. Oculus Rift – developed by Oculus VR, a division of Facebook – came out on March 28, 2016, and with it came a new way of gaming (Robertson 2016). VR uses both regular and movement controllers. The player can still play the game normally but with a 360 degree or using their entire body in the gameplay. When you need to reload a gun in FPS VR, instead of just pressing a button, you have to move your hands to make it seem like you are actually reloading in real life. Even the military uses VR and FPS games to train new soldiers for combat.

First Person Shooter games have come a long way since the 1970s. With more advanced graphics, game engines, artificial intelligence, and virtual reality, FPS will continue to evolve and improve for years to come.

Five Nights at Freddy's, a Point and Click Horror Game

Brian Edington[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Horror game; Point and click game; Transmedia storytelling

Definitions

Point and click game:	An adventure game in which the player interacts mainly with the mouse or a pointing device.
Horror game:	A video game based on the horror genre.
Transmedia storytelling:	A technique of telling a single story or story experience across multiple platforms and formats.

Introduction

Technology has advanced dramatically over the past century, going from giant supercomputers and the invention of the radio to the portable computer better known as a laptop and a small device most people carry daily to do nearly anything we need. The same can be said about video

games, having gone from a colossal arcade machine to a downloadable application on a phone, computer, or console. Some of these games have gone as far as being a part of esports, though some would not and do not fall under that category. Indie horror games are made by either a small team or an individual using horror elements – whether they are terror or gore, or both. One such indie game has made an impact on the future of indie horror games, though it is debatable if it is for the better or for the worst. That game is Five Nights at Freddy's.

Five Nights at Freddy's, also known as FNaF, is an indie horror game released in mid-to-late 2014 by, at the time, a financially struggling game developer known as Scott Cawthon. According to Patricia Hernandez, a writer on Kotaku, "It's been called the 'scariest game in years.' It's at the top of iOS and Android app stores, it has torn up the Steam charts on PC. It has racked up millions and millions of views (and screams) on YouTube. It has hundreds of earnest fan games, and dozens of rabid fan theories" (Hernandez 2015). With each new installment or addition to the FNaF series, the fanbase grew bigger, adding on fan-made songs, remixes, gameplay, original content based on the series, and more. As of 2022, the Five Nights at Freddy's franchise has roughly nine games to its name, three book series based on the games, a movie that has been in the works for quite a few years now, and even an initiative to fund some game developers to work on their projects. Despite what negative or derogatory things some people have to say about Cawthon, his games, or the fanbase, there is no denying that the first game – the game that started it all – is what brought a new form of horror to light.

Gameplay

According to Nadia Oxford, a staff writer for USGamer, "Five Nights at Freddy's (FNAF) is a series of point-and-click horror games for PC and mobile made by independent game developer Scott Cawthon. The game's setting varies from game to game, but the premise between them remains the same: The player, looking through the eyes of the games' protagonists, must stay alive for five or six days against an onslaught of animatronics who want your blood" (Oxford 2021). The player's only defenses are the security cameras in the building, the office door, and the lights. The player has a limited amount of electricity each night. There are no playable characters, battle systems, or skill trees. It is a horror game with heart-pounding jump scares, but without the blood, gore, and extreme violence typically associated with horror films. The player's task is to survive, as the game title states, five nights at Freddy's. The challenges are Easter egg hunting and surviving each night without getting killed by the animatronic characters. Here are the basic steps to play the survival horror game as a security guard working the night shift:

1. Monitor the animatronics using security cameras and lights.
2. Manage limited resources wisely (e.g., Should the player close the doors to be safe or leave them open to conserve battery?)
3. Protect yourself from the animatronics by using a set of tools.

Each version of Five Nights at Freddy's offers a different set of tools. For example, in Five Nights at Freddy's, the player can control the two security doors connecting their office to the adjacent hallways as a barrier against animatronics in the vicinity. However, in Five Nights at Freddy's 2, there are no protective doors. Instead, the player must use an empty animatronic head and flashlight to defend itself against the animatronics. Five Nights at Freddy's 3 offers a monitor panel, which contains audio, camera, and ventilation. The common elements across the different versions are security cameras, lights, doors, vents, jump scares, mini games, phone calls, Easter eggs, and location closings.

Reception

At first, FNaF did not receive a lot of attention, but Cawthon's luck would turn around soon enough. A YouTuber/theorist who goes by FuhNaff created a video about the history of the FNaF franchise, its humble beginnings, its rapid rise in popularity, and its ever-increasing amount of content. In the video, he mentions that the game's first demo was released on a site called IndieDB but hardly anyone played the demo, except for an unknown YouTuber at the time, who was given the full game by Cawthon himself. Fast forward to August of that year, Cawthon released the full game on another site called Desura where another YouTuber, more well-known back then, did a "Let's Play" on the game, and it started to get noticed. People began to adore the game. With a growing audience and the more popular YouTubers playing the game, FNaF keeps expanding the fanbase (FuhNaff 2022).

Conclusion

Five Nights at Freddy's became a huge success after its slow start, racking up millions of downloads on various websites and mobile phones. FNaF has become an icon in certain parts of the gaming community, being recognized as an old game that some might consider it a game that should have lost traction long ago, while others see it a continuous story to be solved by the community as long as they find the right clues to solve the mysteries of the old haunted pizzeria.

The game has spawned a novel trilogy, the Fazbear Frights series, and the Tales from the Pizzaplex series cowritten by Scott Cawthon as well as graphic novels adapted and illustrated by other authors. A film adaptation was announced in August 2022 that the script had been written by Cawthon, Emma Tammi, and Seth Cuddeback, and the film will be produced by Blumhouse. Five Nights at Freddy's is a prime example of transmedia storytelling across multiple platforms and formats.

Computed fluid flow

Definition

Simulation of fluid flow based on real-time computation on a workstation using different assumptions to approximate the overall behavior of the fluid.

Introduction

Digital simulation has been a well-explored research topic over the last decade. In particular,

the simulation of natural phenomena like fluid movement has attracted a lot of attention. There are mostly two different kinds of fluid simulation. One is for realistic movement of fluids in a high-performance computing area, and the other one is a real-time fluid simulation with desktop workstations. This literature review should give an overview on existing work in the field of real-time fluid simulation and the differences between different fluid representations. In the last decades, we can observe three different classes for real-time fluid simulations. The first one is dealing with fluid in a height-field environment that is very simple – but – yet efficient approach. This approach has drawbacks to show more sophisticated effects like splashing and bubbles. To calculate the fluid flow in all dimensions makes the simulation less efficient but enables to show effects like particles. Last but not least, the particle-based approach is the more recent one where each particle is a sample of the fluid flow, and with this samples the overall fluid flow gets approximated.

Related Work

In this entry, we overview various classes of fluid representations currently used for commercial applications in computer graphics. Three techniques are most commonly employed: *height field*, *cubic Eulerian grid*, and *particles*. Each family of fluid representation exhibits different characteristics that can fit different application demands. For a more specific introduction about existing techniques for fluid simulation, we refer the reader to one of the most comprehensive books about fluid simulation published by Robert Bridson (2008).

Particle-Based Fluid Simulation

The class of particle-based techniques uses a set of independent particles that approximate the fluid flow function by discrete values. The critical SPH drawback is the amount of computation time needed to process a large set of particles. The seminal work for SPH is described by Premoze et al. (2003) introducing a particle-based representation for fluid simulation and comparison to the traditional grid approaches. Later, numerous SPH techniques were presented following the same principle. For instance, interested readers are referred to the survey of Ihmsen et al. (2014). Then, we propose to detail various key features of existing SPH techniques: *surface tension*, *surface meshing*, *bubbles and foam*, *level of details and multi-scales*, *solver convergence*, *multiple liquids*, and *elasticity material*.

Surface Tension. The surface tension comes by design while using a height field for fluid simulation. In contrary, surface tension should be explicitly defined while relying on particles as claimed by Yu et al. (2012) and Schechter and Bridson (2012). Both papers present two different types of particle-based simulation that just not track particles for fluid simulation but also employ particles for modeling airflow around the fluid surface. Defining two kinds of particles and making them interact with each other enable to simulate surface tension. Furthermore, Yu et al. (2012) present a surface tracker to map particles into meshes, and Akinci et al. (2013) propose a method to simulate large-scale surface tension. However, Busaryev et al. (2012) extend the idea to use different particles to represent droplets and bubbles. Finally, using different particle types for different specificities is a very promising way to simulate natural phenomena in particles.

Surface Meshing. A major difficulty with particle-based fluid simulation is to transform free particles into a mesh for visualization and then render them without flickering artifacts. This problem is even more challenging to solve in the presence of splashing fluid. Yuksel et al. (2007) realized wave simulation and convert particles into a height field for fast rendering. To calculate collisions with the fluid particles, Akinci et al. (2012) propose a two-way coupling method for SPH fluids, using particles inside the solids. Also, a collection of previous works (Hoetzlein and Höllerer 2009; Batty et al. 2010) generate meshes from particles. Still, the problem of generating triangular surface meshes from particles remains a challenging problem with active research. For instance, Wojtan et al. (2010) introduce a mesh-based surface tracking method for

particle-fluid simulations. Finally, Ando et al. (2013) introduce a tetrahedral discretization for the pressure projection and a method to extract a smooth surface from particles.

Bubbles and Foam. Thanks to the computational power available on standard workstations nowadays, particle-based simulation offers more sophisticated natural phenomena and realistic effects like bubbles and foam. A collection of previous works (Hong et al. 2008; Cleary et al. 2007; Kim et al. 2007) simulate bubbles with SPH fluid simulation. The key idea is to mix bubble-labeled particles into the overall particle-based fluid. Moreover, Busaryev et al. (2012) extend the classical particle-based liquid simulation by incorporating bubbles inside the foam. To simulate a bubble effect with higher realism, the connectivity information of a Voronoi diagram should be built over the foam particles.

Level of Detail and Multi-scales. Levels of details are employed to speed up rendering while increasing the realism as much as possible with respect to available computer power. For instance, Solenthaler and Gross (2011) improve standard SPH by varying particle size at different regions of the scene to be simulated. The key idea is to use smaller particles where more details are needed, for instance, at collision location with obstacles and larger particles far away from the camera. In this direction, Yu et al. (2009) present view-dependent levels of detail technique to deal with large-scale scenes representing rivers with particle simulation in real time. Recently, Zhu et al. (2013) rely on an extendable dynamic grid to improve the efficiency. Finally, Edwards and Bridson (2014) introduce an adaptive fluid simulation enabling simulation at high resolution without the need of a fine discretization for the entire field.

Solver Convergence. Some techniques focus on increasing time steps for particle-based fluid simulation. For example, Macklin and Müller (2013) improve SPH fluid simulation with surface tension toward a better convergence and a constant density, allowing larger time steps using fewer particles. Finally, Solenthaler and Pajarola (2009) increase the time step of SPH fluid simulation by incorporating the particle pressure.

Heterogeneous Liquids. A collection of works allows the simulation of multiple liquids at different densities and viscoelastic properties inside the same simulation (Losasso et al. 2006; Ren et al. 2014; Shin et al. 2010). For instance, Lenaerts et al. (2008) present a SPH fluid technique to flow through a porous deformable using nonlinear materials. Also, Batty et al. (2007) combine fluid and solid with irregular boundaries. Recently, Robinson-Mosher et al. (2008) prefer to merge the momentum together.

Eulerian Grid Fluid Simulation

Another well-known class of approaches for fluid simulation is the 3D Eulerian grid. An important property of the Eulerian grid is its ability to represent complex 3D effects like splashing. Unfortunately, the quality of the fluid effects is limited by the grid resolution. An important work introducing 3D Eulerian grids is Chentanez and Müller (2011) using cubic grid cells to demonstrate complex 3D fluid effects. Lentine et al. (2010) improve the Eulerian fluid grid by dynamically adapting geometry from a given coarse grid. However, Brochu et al. (2010) prefer to rely on a Voronoi mesh interpolation, starting from a Eulerian liquid simulation. Also, Thürey et al. (2010) extend the Eulerian techniques by incorporating surface tension to offer more controllability over the fluid. Moreover, Raveendran et al. (2012) employ a sparse mesh to control fluid simulation. More recently, few works improve Eulerian liquid simulation by tracking fluid details (Bojsen-Hansen and Wojtan 2013) finely and enhancing the visual quality of the fluid simulation without using a finer grid (Zhang and Ma 2013). Finally, we notice that Eulerian-based fluid simulation is not often employed in production as a single representation, because of its inherent limitations. Thus, Eulerian grids are combined with other techniques to form hybrid solutions (as detailed in section "Hybrid Fluid Simulation").

Hybrid Fluid Simulation

We observe the high demand of hybrid techniques combining different fluid representations to produce large-scale simulation with fast

computational time and fewer memory requirements. For instance, an efficient strategy is to start with a height field as input to allow rendering of large-scale scenes and then to switch to more sophisticated approaches in the case where more details are required. Outstandingly, it is feasible to combine height-field, Eulerian, and particle-based methods to obtain efficient, stable, and flexible fluid simulation for breaking waves, waterfalls, and splash particles. Hybrid techniques enable high details on large water simulation in real time by switching between the different fluid techniques. One of the first hybrid fluid simulation techniques was proposed by O'Brien et al. (1995) combining height-field fluid simulation with a particle-based approach to generate spray effects. Later, this approach was improved by Chentanez and Müller (2014) by adding stability constraints and a combination with 3D Eulerian grid (Chentanez and Müller 2014). Finally, we notice that hybrid strategies improve the quality and flexibility of fluid simulation.

Fluid-Oriented Height Fields

Height fields are often used to represent simple surfaces thanks to its simple structure and fewer memory overheads. This representation is commonly used for game terrains and can be easily adapted for LOD and tiling. Height fields are an important class of fluid simulation motivated by an efficient use of resources. We refer interested readers to the excellent introduction of Cline et al. (2013) to the concepts of fluid simulation on height field. Also, we highlight two seminal works. Kass et al. (1991) approximate the shallow water equation to simulate wave refraction with depth, net transport of water, and boundary conditions with changing topology. Moreover, Stam et al. (1999) animate fluid in real time by splitting and simplifying the Navier-Stokes equation. More recently, Nielsen et al. (2013) synthesize waves, while resolving mesh self-intersection.

Mikls et al. (2004) introduce a computationally efficient layered water model to approximate the upper and lower water surface, allowing 3D water effects, like water flowing into a jar. More recently, Nielsen and Bridson (2011) introduce constraints on which a fluid simulation keeps close to a guided fluid simulation and to produce a predictable fluid simulation. For instance, Foster and Metaxas (1996) use height field for rendering effects like wave reflection, refraction, and diffraction. Also, Klein et al. (2003) describe how noise-based animation improves the appearance. Moreover, Müller-Fischer et al. (2008) reduce the computation time for a fluid simulation to be used in real-time applications like games. The key idea is to employ 2D height field with low resolution coupled with realistic shading effects, while freezing the simulation at non-visible regions. Finally, Yuksel and Keyser (2009) improve the visual appearance of height-field fluid simulations with real-time caustics using a generated caustic map.

Conclusions

All fluid techniques have their advantages and disadvantages. There is still a lot of ongoing research in the field of fluid simulation. At all techniques, we have observed that the time step between two iterations is critical. A too long computation delay damages the simulation in the form of stability or unpleasant visual results. Height-field fluid simulation is a simple and long-standing fluid simulation technique developed for computer graphics but is still very often used. The particle approach is newer with a lot of ongoing research which tries to fix known drawbacks to make the simulation even more realistic. Very interesting is the idea to combine the different fluid approaches to a hybrid approach. This helps to avoid the drawbacks of the different techniques but introduces more logical complexity to the fluid simulation. Overall, fluid simulation is still an attractive research area where no perfect solution exists.

Definition

Fortnite = a video game that has two game modes: a co-op zombie survival mode and a Battle Royale mode.

Fortnite Friday = a weekly Fortnite tournament organized by Daniel "Keemstar" Keem and Faze Clan founder Ricky Banks.

Fortnite World Cup = an annual e-sports competition based on the video game Fortnite.

Introduction

This entry covers the history of Fortnite with the focus on the Battle Royale mode. It includes the story of live streamers who brought popularity to the game, the advantage Fortnite had over other

Battle Royale games, the start of Fortnite Friday, and the Fortnite World Cup. The entry concludes by discussing the effect Fortnite had on other games in the same genre and different genres.

Gaining Popularity

Fortnite was first released for early access in July 2017 with only one game mode: Save the World, which is the co-op zombie survival mode. When it launched, it did not gain much popularity with few people live streaming it. That all changed on September 26, 2017, when they launched their new Battle Royale game mode. It brought new players and streamers to the game because this game mode catered to a new audience of players who enjoyed third-person competitive shooters. After the release of the Battle Royale, more players and streamers started to take notice of Fortnite. One such streamer was Tyler "Ninja" Blevins with his flashy playstyle and skill that seemed to be greater than everyone else. He started to gain popularity not only for himself but also for Fortnite as well. Ninja went on to become the first streamer to get his own skin in the game that featured his iconic spiked blue hair and yellow headband (Rishabh 2020).

Fortnite's Cross-Platform Play and Free-to-Play

Fortnite had several advantages over other Battle Royale games that helped propel its popularity. When it was first released in 2017, Fortnite was the first Battle Royale game available on both the PC and the consoles. This gave Fortnite a huge advantage because it attracts not only PC players but also PlayStation 4 and Xbox One players. Fortnite was later released on mobile devices and Nintendo Switch as well, making it playable on almost any platform. Sony who owns PlayStation refused cross platform play at first, but in 2018 Sony decided to allow their players to join the PC and Xbox One players in playing Fortnite (DigiZani 2021). Since day 1, Fortnite is free to play, making the game accessible to every gamer in the world.

Fortnite Fridays

Fortnite Friday is a weekly Fortnite tournament organized by Daniel "Keemstar" Keem and Faze Clan founder Ricky Banks. (Faze Clan is a professional esports and entertainment organization founded in 2010 and headquartered in Los Angeles, California.) In this tournament, two teams of two – comprised of either a Twitch or YouTube streamer or a big-name celebrity – would compete in a best of three series where they played in the same game and competed to be the duo with the most kills for that game. There were ten tournaments over 10 weeks, each with a prize pool of $20,000 (Twin Galaxies 2021). This brought attention to the community's desire for a competitive scene in Fortnite's Battle Royale mode. The tournaments even attracted the attention of the famous rapper Drake who gave a shout-out on Instagram to Brett Squires who was competing. Forbes and ESPN both took notice as well writing stories related to the weekly tournaments (Erzberger 2019).

Fortnite World Cup

In July 2019, Fortnite held it biggest event to date beginning on July 26 and lasting through July 28 with four tournaments and a whopping $30 million prize pool. The tournament venue was Arthur Ashe Stadium where the US Open for tennis is hosted. But for those 3 days, the stadium was home to thousands of Fortnite fans cheering on their favorite Fortnite competitors. Competitors had to go through a 10-week qualification before they were able to compete in the tournaments.

Outside the stadium was a miniature Fortnite amusement park featuring a zipline, mini-golf course, a giant pirate ship, and a giant ball to roll around in. In between the tournaments, there was a Marshmello concert and teases of the tenth season of the game.

Even with all those things going on, the main attraction of the event was still the competition. The four tournaments played during the event were a creative mode showcase, celebrity Pro-Am, duos championship, and a solo championship featuring 100 of the world's best Fortnite players. The duo and solo championships were what most people came to watch as they were going to show the highest level of play that had ever been seen. A European duo of Emil "Nythrox" Bergquist Pederson and David "aqua" Wang won the 3-million-dollar duo competition; 16-year-old Kyle "Bugha" Giersdorf won the 1-million dollar solo competition (Webster 2019).

Fortnite's Influence

With Fortnite becoming one of the most popular games in the world, it is natural for other games to try to copy its success formula. One popular feature in Fortnite is the battle pass system, which is essentially a system that rewards players for playing the game and offering more rewards for players who decide to upgrade to the paid version of the battle pass. The free to play model with microtransactions to customize the game has also become a popular feature with the success of Fortnite.

Conclusion

Fortnite had a slow start in July 2017 with the Save the World mode, but it quickly gained popularity with the launch of the Battle Royale mode in September 2017. With the introduction of Fortnite Friday, the competitive scene was beginning to develop, which led to Fortnite World Cup in July 2019 – the biggest event in Fortnite history. Fortnite will go down as one of the most influential games in history.

Definitions

The *medium* of virtual reality (VR) can be defined as the unique set of practices and novel affordances that emerge when using VR and is distinct from work built for screen-based or other media.

Introduction: VR, a Technology, and a Medium

VR systems bring together a family of technologies to create a convincing computer-graphical space around the user. These spaces can range from the photorealistic to the abstract and can include a host of objects, interactions, and effects. While many VR systems are primarily visual (the focus here), others can involve other sensory modalities such as haptic or olfactory feedback. Better understanding VR as a technology and as a medium will aid in distinguishing between media technologies, genres for using such technologies, and particular works. *Technologies* here refers to hardware and software that are researched, developed, and used. A *genre* is a style of using some input/output capabilities, and a *work* is an instance of a genre" (Goguen and Harrell 2014). The *medium of VR* can then be defined as the unique set of practices and novel affordances that emerge when using VR. Genres of VR will continue to emerge as conventions are innovated and established. Works created that uses the *medium* of VR will be distinct from work built for screen-based or other media. This understanding of VR is especially important for understanding its role as a medium for works of computer-based art (Bates 1992) such as videogaming and interactive narratives (Jenkins 2004; Thiel 2009).

The *technology of VR* can be defined as any combination of devices and software that produces a sense of virtual *exteroception* and *proprioception* in a user. Exteroception refers to perception of an external environment. Proprioception refers to perception of one's own body (Fotopoulou 2015).

These technologies most typically include: (1) real-time computer graphics, (2) dynamic visual interaction including: a panoramic image space with positional and orientation tracking, (3) sensory elements including stereoscopic vision, a head-mounted viewing device, and spatial audio, and often (4) motor elements including peripheral devices such as handheld controllers. These elements combine to produce a sense of *virtual exteroception*, providing a sense of a tangible virtual environment, and of *virtual proprioception*, providing the sense of a tangible virtual self. VR can include less interactive work, such as 360-° film, or highly interactive work, which could include peripherals such as gloves equipped with sensors and treadmills to simulate physical movement.

This section introduces definitions of these various technologies, discusses their key aspects, and demonstrates examples of how each – individually and in combination – provide unique impacts on creating VR systems.

F

Real-Time Computer Graphics

Real-time computer graphics are familiar to most users from media forms such as computer games and animated feature films. However, while animated films often use pre-rendered computer graphic images (CGI), VR environments and models are rendered as-needed in response to user input such as gaze, position, movement, and gesture while users explore and interact with the virtual environment. VR experiences can be built from 3D models and environments implemented synthetically using CGI software. Alternately, VR imagery can be captured from the physical world through techniques such as photogrammetry and videogrammetry to build 3D models from photos and video. Finally, VR environments can be created using techniques integrating both synthetic modeling and physical world capture-based modeling. For example, in *Hospital with One Entrance,* artist Deniz Tortum uses a laser scanning device to capture the physical dimensions of a hospital's operating room and then imports these data into VR software to program interactivity (Tortum 2016).

Key Graphics Technology Considerations

Computer graphics used in VR require a frame rate of up to 75 frames-per-second (fps) in order to ensure smooth movements and avoid noticeable *judder* to the user. Systems that fail to provide high quality resolution and frame rate cause end users to perceive *judder* and may result in motion sickness. Given these requirements, VR computer graphics systems must be equipped with powerful enough graphics processing unit (GPU)

capabilities and have low system *latency*, or time between user input and updates in displayed graphics.

Key Graphics Design Considerations

Real-time graphics provide both constraints and affordances for designers. Latency and judder are examples of *constraints*.

System designers must negotiate these constraints, for instance, *tethering* consumer VR headsets to powerful GPU-packed computers using cables. These challenges have inspired research and development efforts focused on designing more efficient hardware to enable higher-quality VR experiences on affordable mobile devices with less processing power. Given that VR systems enable the design of nuanced interfaces and experiences tailored to individuals based on their gaze, position, movement, and gesture over time, overcoming power and latency issues enables more impactful uses of the medium in educational, training, medical, and therapeutic contexts (Chu and Cuervo 2016; Lai et al. 2017).

Orientation and Positional Tracking

Users can navigate their visual environments more freely in VR than in other screen-based media. This is due in part to the combination of a panoramic virtual environment with orientational and positional tracking. Positional tracking and orientation tracking refer to the ability of VR systems to track user movement in the physical world, and translate that movement to the virtual environment. The degrees to which VR systems support translating user movement from the physical world to the virtual environment is referred to as the "degrees of freedom" (DOF) of the system. *Orientational tracking* means that the system tracks the rotational movement of a viewer's head, thus allowing a user to look freely in any direction in the virtual environment. All current VR systems enable orientational tracking. *Positional tracking* follows the user's translational motion and positions the user in a 3-dimensional environment. Higher-end VR systems enable positional tracking. These types of user tracking, combined with the complete panoramic image space and a wide field-of-view, create a visual environment for the user that is closely connected to natural perceptual activities. Moreover, in VR, the CGI spatial environment also implies shape, volume, location, and physics, encouraging users to look under, around, or through elements in space (Smith 2017).

Key Tracking Technology Considerations

Positional tracking in VR is generally achieved through sensors which may be internal or external to the head-mounted display or controller. Some hardware also uses embedded sensors to track this kind of motion. *Orientation tracking* is typically tracked using a combination of accelerometers, gyroscopes, and magnetometers embedded into the hardware. For positional tracking, laser- or camera-based sensors can be used. Each of these technologies has tradeoffs for design: for example, camera-based systems can be more accurate, but require processing power and connections sufficient to avoid latency and have additional privacy considerations.

Key Tracking Design Considerations

Positional and orientation tracking activate the visual space outside the user's immediate field of view, allowing users to glance and reach at things in the periphery of their vision and to lean or reach towards and away from elements in the scene. *Intentional looking* and *direct address* are two techniques for accounting for this in design. For example, consider a VR experience in which the spatial imagery around the user initially goes pitch black and then lights flicker on a little bit later. The user might react by looking curiously around using and investigating the full panorama image space to see what changed. The user's investigation of the space is motivated and intentional, more active than receptive. *Direct address* describes the "two-way process of a user both seeing and being seen" by other characters within the environment and by the virtual environment itself (Sutherland 2015). The tracking devices allow the system to change in response to a user's attention: for example, objects appearing only when the user is gazing elsewhere.

Placement of objects within the environment given the constraints of the positional tracking system and the *tethered* display is of key concern when designing for HCI in VR. For example, while activities such as "crouching" or "crawling" in VR games can provide an exciting sense of immersion, they can easily result in user fatigue if repeated too often during the experience.

User tracking and spatial design also has emergent effects in multiuser environments. For instance, nSpace is a project exploring collaborative aspects of VR for design tasks. This system uses a special sensor for hand tracking to visually represent the user's hands. This enables interaction with user interface components that exploit the 360 ° visual representation. This enables users to move through virtual environments and provide more specific and relevant feedback on objects and instructions to other users using *subjective* – in relation to a user's body (Johnson 1987; 2007) – rather than *objective* language, such as the absolute position of an element on a screen (Zaman et al. 2015).

Stereoscopic Vision, Head-Mounted Displays, and Spatial Audio

The combination of stereoscopy and head-mounted displays (HMDs) connects VR systems closely with natural visual perception. Stereoscopic vision in VR produces the illusion of depth and three-dimensional space and is achieved by displaying parallax angles of images through dual lenses. These dual images originate from different perspectives and slightly overlap, such that users fixating binocularly on a point will perceive elements images on the same relative coordinates as a single object (Tam et al. 2011).

HMDs must also be equipped to deliver spatial audio that is synchronized with the visual experience. Finally, many companies and researchers are working towards enabling eye-tracking in consumer VR systems.

Key Stereoscopy, HMD, and Spatial Audio Technology Considerations

As discussed above, most consumer VR headsets are *tethered* to powerful GPU-packed computers with high power consumption and thermal output. However, active work is being done to develop more efficient HMDs that can deliver higher-quality VR experiences on more efficient and wireless devices. HMDs can also deliver spatial audio which simulates natural human localization techniques using sound clues. The widespread use of consumer speech recognition systems, work in 3D binaural sound reproduction, and spherical microphones are advancing the quality of spatial audio capture and playback (Jarrett 2017).

While eye-tracking adds an additional computational load to systems, it can enable *foveated rendering* techniques, which are processes for reducing the workload on the system by high-quality rendering of the graphics the user is looking at and lower-quality rendering of the visuals in the user's peripheral vision (Guenter et al. 2012; Padmanaban et al. 2017).

Key Stereoscopy, HMD, and Spatial Audio Design Considerations

Stereoscopic depth enables VR to convincingly situate users in CGI spatial environments, resulting in a sense of a physical relationship to objects and characters (Schröter 2014).

Tethered HMDs limit users' range of translational motion, but research and releases to the consumer VR market are trending towards improving phone-based, wireless, all-in-one HMDs. As barriers to entry for VR HMDs become lower, HMD design must anticipate and address the "brick in the face problem" which results from the opaque quality of the headset.

Given that the eyes provide a crucial means of nonverbal communication in social contexts including gaming, eye tracking technology can be used as input to achieve better customization. Other VR experiences such as *The Enemy*, a journalistic VR artwork by photographer Karim Ben Khelifa addressing global conflict (Kennedy 2016; Lacey 2016), allow for dynamic changes to the experience's narrative (e.g., events and dialogue) and staging (e.g., lighting and mise en scène of the virtual environment) based on the users' embodied input to the system using artificial intelligence. For example, features including users' translational motion, head motion, directional orientation, and proximity to each other

and to virtual characters are used as proxies to track users' attention, nervousness, and biases (e.g., asymmetries of attention and nervousness). This real-time user tracking triggers feedback by the system including changes to behaviors of the nonplayer characters, appearance of the users' avatar, voice-overs, and the virtual cloud cover (thereby impacting the lighting). Eye-tracking capabilities can also enhance the evocative potential of this genre of VR experiences. In social VR, eye-tracking technology has been used in conjunction with computer vision algorithms which align and blend a 3D face model with a camera's video stream of the user (Frueh et al. 2017). These strides demonstrate how artificial intelligence will help to enhance connection and interaction in multiple-user VR scenarios and third-party gameplay viewers.

Furthermore, spatial audio can be a powerful tool to present sounds from any direction, control user attention, give users cues on where to look, and provide an immersive VR experience (Grau 2003). Spatial audio in VR has the potential to be applied as a powerful design tool for evaluating planned architectural designs in combination with soundscapes prior to physical construction (Echevarria Sanchez et al. 2017). Tools such as *Mediate VR* which enable the evaluation of space and soundscape designs through remote, asynchronous, voice-driven collaboration. Forward-looking designs of HMDs must be able to stream and play spatial audio in real-time, with tools such as *TheWaveVR* introducing the concept of social platforms which host immersive VR music concerts.

Peripheral Devices

VR peripheral devices enable additional forms of user input, output, and interaction in the immersive environment. Although not the focus of this article, it is important to consider key types of such devices.

Key Peripheral Device Technologies

Peripheral device input can include the positional tracking of hands and a variety of controller-like inputs. Peripheral device technologies includes *haptic technologies*, which describes a form of human-computer interaction involving touch. These peripherals range from controllers or simple touch screen devices with button-based controller paradigms, to a joystick, remote, or mouse, as well as devices which enable gestural interaction ranging from the 1990s "data glove" (Premaratne 2014), treadmills, to *Leap Motion, Microsoft Kinect,* or the *Myo* armband. Peripherals can also include biometric devices such as wireless wristbands that monitor real-time physiological signals for affective computing interfaces, EEG-based biometrics for brain-computer interfaces and more. Sensory-output-based peripherals may also include vibrating floors and mats, electrical muscle stimulation for muscle-computer interfaces, and olfactory output devices.

Key Peripheral Device Design Considerations

In combination with the technologies presented in the previous sections, peripheral devices present additional design opportunities and challenges. For example, while handheld peripherals and gloves can enable users to manipulate virtual objects, developers must account for the effect of users seeing their own hands. Systems that enable standing in combinations with tracked handheld peripherals afford the user the ability to be able to reach into virtual environments and do things, requiring nuanced handling of embodied input.

By leveraging biometric devices that provide real-time physiological data or manipulate the sensations of the user's body, an additional layer of immersion is added to the experience. For example, recent research has used muscle stimulation through gentle electrical impulses as a new approach to rendering the haptics which afford the repulsion of a wall or gravity pulling down the weight of a heavy box (Lopes et al. 2017).

Creating VR Experiences

Introduction

This section presents two theoretical approaches that can underpin and motivate the design of VR experiences. The first, constraints and affordances, is crucial to organize approaches to the many new interaction paradigms and sheer

variety of design choices. The second, conceptual metaphors and blends, suggests a way to bring metaphorical thinking into the virtual environment in a way that can be used both for creative purposes and for efficient design.

Constraints and Affordances in VR

The technologies that enable the possibilities of immersive VR environments also present both *sensory constraints* and *physical/motor constraints*. *Sensory constraints* are limitations in being able to provide visual information to the user. This may result in a lack of framing around the content of the experience, or a lack of self-representation of the user's body in space. Many VR systems focus on visual and auditory constraints. *Physical/motor constraints*, which are limitations in the physical capabilities of the hardware design, setup, of ability for users to move in the physical world. This may result in a lack of freedom in users' movements and interactions with their physical surroundings, which may result in safety risks.

The psychologist James Gibson provided a useful term when discussing what technologies enable or constrain: he defines an *affordance* as what the environment offers or furnishes to the user (Gibson 1977, 1979). In these terms, VR is a unique medium with the potential for novel interaction mechanisms given the particular constraints and affordances of the technology. In VR, the designer has a close hand in creating and varying the *perceived affordances* presented to individuals within the experience (Norman 1999).

The design choices of developers, in conjunction with the aforementioned technological elements of the medium, also shape the *sensory affordances* of VR systems. Especially of note are their *visual*, *tangible*, and *gestural affordances*. *Visual affordances* are visual cues which invite users for action in the form of visual guides or floating user interface (UI) elements. For example, in any given VR experience, users can have either *no body*, *an object instead of a body*, a *partial body*, their *own body*, *another person's body, or even multiple bodies*. *Tangible affordances* are provided by peripherals which enable *haptic* interaction and cues in the environment, such as different vibration patterns being transmitted to the users' fingertips through controllers or point and click devices. *Gestural affordances* provide cues which invite users for gestural interaction, such as cues to virtually touch or pick up objects.

Conceptual Metaphors and Blends in VR

VR experiences and tools can be thought of as a *performance* between users and their virtual environment (Laurel 2014). One potentially effective way to design such mediation is to build *interface metaphors*, a set of visuals which build on existing notions, actions, and *phantasms* (Harrell 2013) to facilitate meaningful and intuitive interactions in VR. Interface metaphors are in turn grounded in conceptual metaphors, which are mappings between ideas (including mental images) that are grounded in sensory-motor action (Lakoff and Johnson 1980). For example, forefingers and closed hands are typically associated with pointing and grabbing; hence, selecting virtual objects may be achieved by virtually pointing and gathering virtual objects may be accomplished by virtually grabbing.

They key to designing strong interface metaphors is keeping them intuitive to the user (Galloway 2012). Users should be able to infer coherent actions based on these metaphors unless they are explicitly designed for creative effects (for instance, an interaction mechanism that is difficult to perform can be useful to represent a difficult action in a VR game). This can be very challenging in such an immersive environment, given that the user can do and perceive many things. Anticipating the user's inferences is important, and by taking an environmental approach to design one can begin to think this way. Likewise, for creative projects, anticipating users' expectations can allow for the creation of surprising and meaningful narratives.

Conclusion

Virtual reality is an important set of technologies and media. This is because, as the name indicates, its technologies seek to make use of many of the modes of interaction that humans have in the "reality" of the physical world while enabling the new "synthetic" possibilities of the virtual. It has also been said that objects in the physical

"real" world can lose their reality due to layers of mediation (Baudrillard 1995) and experiences in virtual environments can have real physical world impacts ranging from bullying to discrimination (Harrell and Lim 2017). In light of these complexities, VR's technologies and their constraints and affordances must be account for while creatively making, subverting, and adapting them for impactful and powerful experiences.

Game Bot Detection on Massive Multiplayer Online Role-Playing Games (MMORPGs) Systems

Andrea Lanzi
Università degli Studi di Milano, Milan, Italy

Definition

Massive multiplayer online role-playing games (MMORPGs) clients (the players) connect to online servers (the virtual worlds). The servers constantly update the client software with the sights, sounds, and happenings in proximity to the player. Attack against MMORPGs is performed by automatic program, bot, that plays automatically and performs cheating actions

© Springer Nature Switzerland AG 2024
N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

against players' moves. In such a context for bot detection, we identify all types of detection algorithms that are able to recognize the game players that are not human users by using several statistical features (e.g., machine learning, statistics on log analysis, etc.). For example one algorithm can perform a comprehensive statistical analysis of user behaviors defined in game activity logs and then set up several threshold levels that can be used to distinguish between game bots and human users.

Overview

A game bot is a program that plays games automatically instead of human users, typically used for game cheating. Game cheating identifies "Any behavior that a player uses to gain an advantage over his peer players or achieve a target in an on-line game is cheating if, according to the game rules or at the discretion of the game operator, the advantage or the target is one that he is not supposed to have achieved." Cheating can be performed at several levels. For example, it can be done by exploiting a bug in the software or protocol or by exploiting vulnerabilities of various people involved in operating or playing online games. When we talk about game bot, we consider the cheating performed by an automatic program that can play without break; consequently it can accumulate money, items, and score much faster than normal human players.

In the recent years, the use of game bots has become one of the most serious security threats to MMORPGs. In fact a game results in significant damages in terms of the economic game cost. For example, Castronova (2007) studied the monetary damage caused by game bots in World of Warcraft, an MMORPG developed by Blizzard, by considering several aspects including customer service cost, a technical cost for bot enforcement, etc. The indirect cost of game bots was approximately 18 million USD per year. To address these issues, game vendor invests significant efforts to design solutions for mitigating game bot activities (Bethea et al. 2010). The most fundamental point for solving the problem is to have a strong mechanism to identify game bots. Several detection techniques have been proposed by game vendors. In the following, we describe the most practical ones used in the real online games.

One of the proposed techniques is to focus on the detection based on repetitive activities of game bots, which are typically found in game log activity. Such technique shows that game bots frequently repeat certain activities that are different from human user ones. Consequently, using this analysis, researchers proposed a new bot detection framework that uses a metric called "self-similarity measure." Self-similarity is used to show the similarity of user actions as a function of the time lag. This method is designed for finding repetitive patterns, especially periodic patterns of the series of actions and their frequency. The method considers several actions such as moving pattern to provide a strong self-similarity that is able to resist to the changes of target games in their following updates. Another strategy is to construct a model of proper client behavior against which actual client behaviors are compared (e.g., system call model). More precisely remote system calls are compared to a control flow model generated from the binary code during its training execution.

A different approach to protecting against client misbehavior in client-server settings is to ensure that clients manage no privilege state that could affect the server; this is commonplace for games today. This approach is for the client to simply forward all unseen user inputs to the server, where a trusted copy of the client-side computation monitors these inputs directly; this is implemented in the Ripley system. This system replicates a copy of the client-side application on the trusted server, and any event is sent to the replica of the client for execution. The system monitors results of the computation, both as computed on the client side and on the server side using the replica of the client-side code. Any discrepancy is flagged as a potential violation of software integrity.

Another common approach to defeat a variety of cheats against the game bots which involves augmenting the client-side computer with monitoring functionality to perform cheat detection is PunkBuster. Such approach requires consideration of how to defend this functionality from tampering, and some commercial examples have met with resistance from the user community (e.g., World of Warcraft's Warden). More in details, PunkBuster is searching in the local memory of the client a certain pattern that can be a symptom of game cheating. PunkBuster based its own efficacy on pre-built database that contains several cheating behaviors in the form of patterns to search for in memory.

History

Several works on game bot detection using several detection approaches have been published. Ahmad et al. (2009) presented a first study, in 2009, by evaluating the performance of various classification algorithms for bot detection in the game called "EverQuest II." They introduced the terms "gatherers," "bankers," "dealers," and "marketers" for categorizing bots with several characteristics such as demographic data, characters' sequential activities, statistical properties, virtual item transactions, and network centrality measures. At the same historical time, in 2008, Thawonmas et al. (2008) also presented an early study that tried to detect game bots using bots' behaviors such as repeating multiple times the same activities than normal users. Their detection rules were based on simple threshold values. Bethea et al. (2010) presented a defense technique based on symbolic execution, used for analyzing the client output and determining whether that output could have been produced by a valid game client. Their proposed technique cannot detect cheats that are permitted by game clients that do not change their behaviors as seen at the server level. At the same time on the network side, Kang et al. (2012) proposed a bot detection mechanism based on the differences in communication patterns between bots and human users. Kang et al. (2013) also proposed a game bot detection method based on the players' network features. Such methods can detect bots with high accuracy. In addition to individual bot detection, researchers also design mechanism to detect bot groups. Chung et al. (2013) proposed a method that cluster features by behavioral similarities using the K-means clustering algorithm and then detecting bots in each group by using support vector machine (SVM), and Mitterhofer et al. (2009), Chen et al. (2009), and Kesteren et al. (2009) proposed similar methods with general features such as the moving paths of characters, respectively. Those works use the characteristic of game bots to move with fixed routes set up by bot programs. Such methods can be applied to most MMORPGs. More recently new detection techniques have been proposed. For example, in the paper (Lee et al. 2011), the authors extend their works into a more generalized model; while their approaches (Mitterhofer et al. 2009; Chen et al. 2009; Kesteren et al. 2009) simply used the single feature of moving path, they build a generic framework with several features by designing a self-similarity algorithm to effectively measure bots' activity patterns, which was previously used as a means of analyzing network traffic (Crovella and Bestavros 1997) or developing intrusion detection systems (Kwon et al. 2011). Such method is significantly robust to changes in the configuration settings of bot programs compared with existing approaches (e.g., (Mitterhofer et al. 2009; Chen et al. 2009; Kesteren et al. 2009)) because the method focuses on all activities and it represents the state of the art of game bot detection techniques used nowadays.

Conclusion

Game bot detection has changed considerably by the first introduction of the online game technology. Several techniques for cheating have been addressed, and new attack techniques have been invented. The business around the online game

has grown a lot, and the attackers are really focusing on such context since it is right now a new business model that attracts cyber criminals that are active in Internet context.

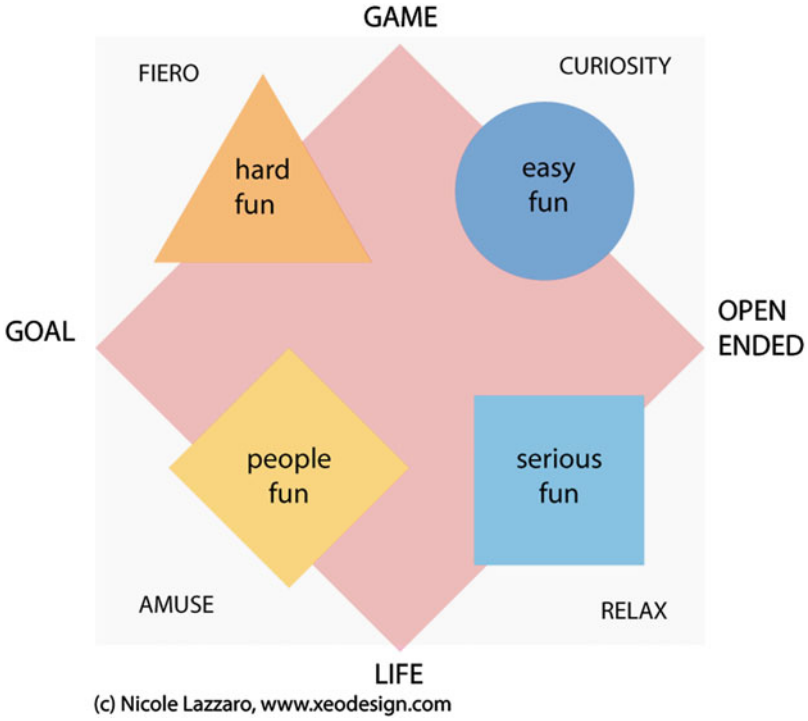
Definitions

Grinding	The process of engaging in repetitive tasks.
Farming	Performing repetitive actions to gain experience, points, or some other form of in-game currency.

Introduction

Evoking a complex emotional response in players is a characteristic trait of successful interactive entertainment, and different models have been proposed to help designers in creating and analyzing compelling emotional experiences. This entry introduces three well-known approaches: the "Four Fun Keys," the "MDA Framework"



Game Design and Emotions: Analysis Models, Fig. 1 Player experience under the lenses of the Four Fun Keys (Lazzaro 2004)

(including the "8 Types of Fun" model), and the "AGE Framework" (including the "6–11 Framework").

The Four Fun Keys

Introduced by psychologist and player experience expert Nicole Lazzaro in the whitepaper "Why We Play Games" (Lazzaro 2004) and later in (Lazzaro 2009), this model identifies four main types of fun with different characteristics which are able to deeply engage players by relying on different sets of emotions. In particular:

- **Hard Fun**: relates to frustration and pride. It involves the act of mastering increasingly difficult challenges.
- **Easy Fun:** relates to curiosity, surprise, and awe. It engages players thanks to visually and content rich environments able to stimulate their imagination.
- **Serious Fun:** relates to excitement and relaxation. It engages players by providing meaning and offering a purpose for the overall experience.
- **People Fun:** relies on social interactions to make players bond in and outside of the game. Here friendship and relatedness become central to the playing experience.

To be successful, games should then focus on one or more of these key types of fun in order to deliver an emotionally rich experience and engage players to the fullest.

The Four Fun Keys are summarized in Fig. 1.

The MDA Framework and the 8 Types of Fun

Proposed by game designers and scholars Robin Hunicke, Marc Leblanc, and Robert Zubek in (Hunicke et al. 2004), the MDA (Mechanics, Dynamics, Aesthetics) was the first serious attempt to discuss games in a more formal and rigorous approach. Central to the MDA is the idea of a game as an *artifact* whose consumption can be broken down into three separate components (Fig. 2):

These, in turn, have design counterparts as shown in Fig. 3 where each abstraction layer is defined as follows:

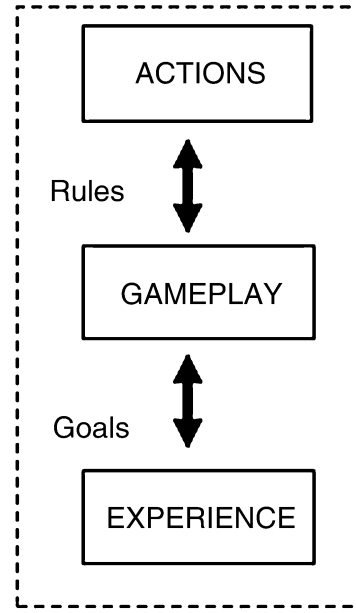
Game Design and Emotions: Analysis Models, Fig. 2 Consumption of games according to the MDA framework

Game Design and Emotions: Analysis Models, Fig. 3 Design counterparts for the elements identified in Fig. 2

- **Mechanics:** the particular components of the game, at the level of data representation and algorithms
- **Dynamics:** the run-time behavior of the mechanics acting on player inputs and each other's outputs over time
- **Aesthetics:** the desirable emotional responses evoked in players when they interact with the game systems

Aesthetics, in particular, is discussed further in a dedicated taxonomy called the "8 Kinds of Fun." These include:

- **Sensation:** game as sense pleasure. This can be created by visuals, soundscape, and proper pacing.
- **Fantasy:** game as make-believe. This is about empowering players and offering new experiences.
- **Narrative:** game as drama. Storytelling helps giving a sense of purpose to the whole experience.
- **Challenge:** game as obstacle course. New challenges, finely tuned with players' own skills, will easily keep them engaged.
- **Fellowship:** game as social framework. Playing with friends is often more engaging than playing alone.
- **Discovery:** game as uncharted territory. This is a fundamental trait of adventure games.
- **Expression:** game as self-discovery. Typical of sandbox games where players are free to experiment as they please.



Game Design and Emotions: Analysis Models, Fig. 4 Schematic representation of a generic game according to the AGE framework

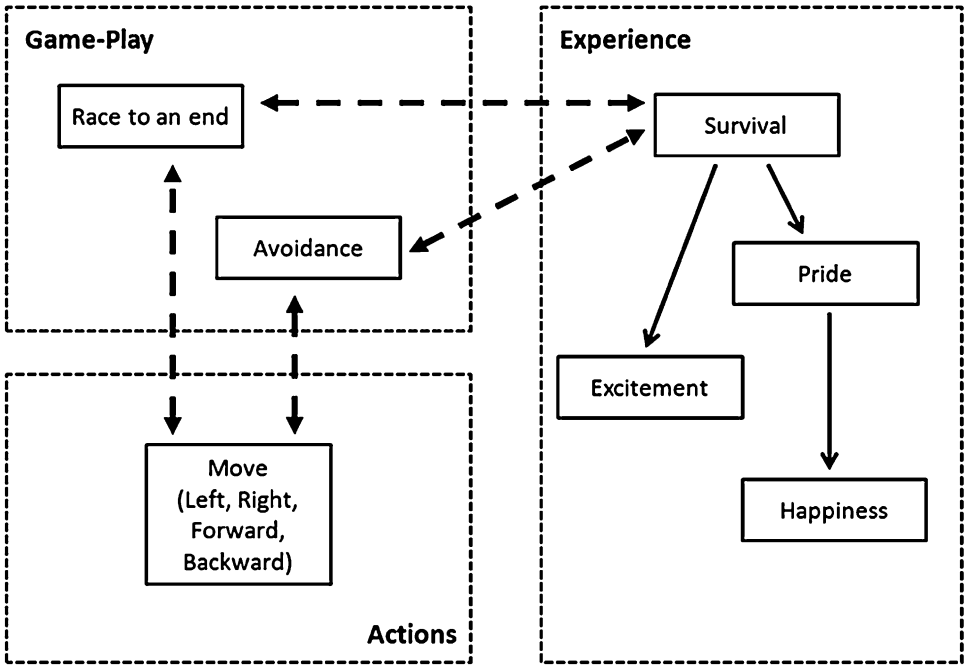
- **Submission:** game as pastime. It may involve grinding or farming and can be used to balance "Challenge" to change the overall game pacing.

For example, a game like "The Sims" (see https://en.wikipedia.org/wiki/The_Sims) can be discussed in terms of discovery, fantasy, expression, and narrative, while a game based on the "Final Fantasy" (see https://en.wikipedia.org/wiki/Final_Fantasy) franchise would be most likely centered on fantasy, narrative, expression, discovery, challenge, and submission.

The AGE and 6–11 Frameworks

The 6–11 Framework was first proposed by game design Professor Roberto Dillon in the book *On the Way to Fun* (Dillon 2010) and then formally integrated into a MDA-inspired model named AGE (Actions, Gameplay, Experience) in (Dillon 2014).

The model describes a game as three main systems (see Fig. 4) interconnected to each other via in-game rules and goals and defined as follows:



Game Design and Emotions: Analysis Models, Fig. 5 AGE Framework analysis for the 1981 Konami arcade game Frogger (see https://en.wikipedia.org/wiki/Frogger)

- **Actions**: the core, atomic actions a player can perform in a game, usually described in terms of verbs. Examples are moving, jumping, kicking a ball, punching, shooting, taking cover, etc.
- **Gameplay**: the resulting play that players achieve by using and combining the available actions according to a predefined set of rules. These can be either higher-level concepts or verbs, for example, fighting, race-to-an-end, territorial acquisition, etc.
- **Experience**: the emotional experience that engages players during the game while trying to reach certain goals, overcoming obstacles, or solving problems.

The experience is then exemplified, thanks to the 6–11 Framework, which comprises 6 basic emotions and 11 instinctive behaviors such as *Anger*, *happiness* (*or joy*), *fear*, *sadness*, *pride*, *excitement*, *survival*, *curiosity*, *self-identification*, *protection* (*or caring for*), *greed*, *aggressiveness*, *revenge*, *competition*, *collecting*, *communication*, and *color appreciation.*

The underlying idea of the model is that a subset from the emotional palette outlined above can be triggered by the game and then can interact with other elements as the game progresses, engaging and motivating players throughout their playing sessions. Once the experience is outlined, one or more of its components can then be linked to the gameplay for analysis and discussion purposes, allowing designers to formalize their ideas and overall vision (see Fig. 5, for an example).

Different game genres may emphasize a different set of emotions, and the model can be applied to serious games as well (Dillon 2013).

Game Development Leadership Tips

Paulo Zaffari
Hoplon Infotainment S.A., Florianopolis, Brazil

Definition

Leadership is the craft of inspiring and guiding people to achieve an objective. In game development, this objective is completing a game within time using the allocated budget while presenting great quality.

Introduction

Video game development has deeply technical details inherently related to it. The most basic of them is the hardware on which the game will run. It will shape, in part, the software and often artistic assets.

There are also more subjective points related to it like: how fun is it, how beautiful are its graphics, how good is its music or sound, and how good is the composition of all the above items. The game story and the many subtleties of the craft can also be summed to these elements.

There is still one factor that is decisive for the success of failure of the vast majority of games: the people who make those games. While many games had great ideas and teams behind them, capable of producing all a great game needs, many of them still failed to deliver as a good product.

There are certainly many explanations for why they failed. When hearing such teams, they will often refer to the lack of a common vision, communication problems, micromanagement, and other problems which are clearly not related to

the game itself (DeMarco and Lister 1999). This category of problems is game production related.

Among the many things needed for a game production process to succeed, leadership is a major facilitator. In this text, a few leadership tips will be presented in order to give a head start to any leader working in the game industry or person seeking education on the topic. Those tips are pieces and bits of information and ideas I came up with during my 10 years of experience in leadership positions in game development.

Tip 1: Love

The love in question is much similar to the one parents, more often than not, have for their children: They want their children to grow and to achieve their dreams. They will provide whatever subsidies on their reach.

More reason for this the similarity with parental love being a working technique and value for leadership is the psychological mechanism of transference and countertransference. Leaders will be in a position where their approval to their subordinates will effectively affect (Stone et al. 2000), if not their chances of survival (Stone et al. 2000) or quality of life, at least their work life. This has a strong similarity to the relationship between parents and their children.

The people working under the leaders will often, therefore, try replicating the relationship they had with their parents with their leaders, due to the transference mechanism. This means their expectations, at least in a subconscious level, will be similar to those they had with their parents.

Sometimes their relationships are or were troubled, causing some degree of hostility toward the leader. Often those relationships were based on love and trust.

Leaders acknowledging this should be prepared to gracefully handle hostility and manage the expectations of their subordinates. The hostility handling may have positive impacts on the person often going beyond the work environment, similar to the effects of a therapy session. Once the leader gets through with it, which may not be always possible, strong bonds are often formed.

Loving the people they command is a value some successful leaders have. More than a practice, this value guides leaders into intuitively relating well to many people as well as shaping policies and actions that foster a healthy work environment.

Finally, it's not without a reason that love is the central value within religions. It had deep appeal for the human psyche, and it's a strong element that leaders should keep in mind.

Tip 2: People

A very common mistake committed by new team leaders, especially those from an engineering background, is not figuring out their work instruments changed. Someone working in the game industry will often be a person whose working tools are programming languages, digital content generation tools, source control systems, and IDEs. Once promoted to a leadership position, this can change overnight: The working instruments of a leader are the people.

This change has often deep implications: Where once a person's job was to implement some feature or create content, the leader is now responsible for getting some other person to do so. This requires a fundamental change in the kinds of skill used and sometimes mentality.

Instead of answering how something should be done, a more appropriate question for a leader to answer is: Who would be the best person or people to do it at this time? Answering this question requires the leader to understand the talents of each individual on his or her team. The leader should be able to answer: "What is a person good at?"

Still, answering properly who is the best person to do a given task takes more than just understanding the skills of each individual. Sometimes even highly skilled team members will not perform well on assigned tasks.

One of the common causes for it is motivation, or rather the lack of it. Determining what motivates a person is, therefore, also a key factor for being a good leader. While motivation factors can vary from person to person, there are some which

are commonly reported and, for this reason, can be addressed proactively by the leader.

One such motivation element exists when someone doesn't understand the goal of a given task; this person will often be unable to evaluate how good a solution is or, at times, even if the solution is correct. While some individuals will ask for the information required to clarify what they need, a good leader cannot assume this to be the case. Proactively ensuring people have enough context is a crucial part of the job.

Another factor is that one has to work with people he or she prefers not to. This might, at least, put strain on the shoulders of those doing it. Understanding the affinities of a team and dealing with them can be a vital part of distributing tasks and, thus, of being a leader in game development.

Also, even when the leader chooses the right person for a task at a given time, circumstances may change during its execution (DeMarco and Lister 1999). From unpredicted technical difficulties to personal dramas, there is a whole universe around this chosen person which can change. A good leader should always be attentive to his or her team members, being always ready to help them whenever possible.

As a reminder, dealing with people involves far more than logic, algorithms, task allocation, or aesthetic sense. It involves questions like self-esteem, sensitivity, sense of righteousness, pride, and many others to be listed. The tool to deal with all of them is communication.

Tip 3: Communication

When working with people, the most important tool to use is communication (DeMarco and Lister 1999; Acton 2014). It should be done far more often than what would feel natural to a leader: Many things which are obvious to the leader may be even counterintuitive to some team members.

Other times, people will simply not tell the leader when they disagree or have problems with something. Considering the issues tolerable, they will often prefer to avoid conflict in order not to look bad in front of the leader or even do it in attempt to become the boss (Stone et al. 2000). This is often a problem, as it may lead into growing tension over an accumulated set of small things.

Worse yet, what may feel like a small problem to some of the team members can, in fact, be perceived as something big for the leader. Also, possibly even more worrying is the opposite case: when something small for the leader feels big for the team member. As there is an undeniable power relationship, this can make the subordinate feel fear.

No good relationship, personal or professional, comes from fear. So, it is an important part of leadership to handle communication properly: both in the sense of content and form.

One possible point to start with, regarding communication, is the tone of voice used. Much of what humans communicate is nonverbal, and the tone of voice, for instance, is a very important factor. Care must be taken to pass the correct information.

Apart from the tone of voice, a leader must ask for feedback and give feedback whenever possible (Acton 2014). It's usual for a team member to be passive on giving or asking for feedback. The leader should be prepared to proactively work around it.

A good instrument for feedback is having periodic one-on-one meetings with each and every team member periodically Stone et al. 2000; DeMarco and Lister 1999). Their objective should be having a human exchange, to prevent possible latent tensions from rising.

Performance feedback should, ideally, be given in a task basis, or even in a subtask basis for long tasks, especially if this means for the leader to demonstrate multiple times a day approval for a well-done job. Showing disapproval is just as important: The earlier the leader shows it, the earlier the team member can correct the cause of it. A good leader should always keep in mind that when he or she does not communicate criticism, it is denying a chance to the person receiving it to improve.

Finally, if a leader gives enough context to the team members, passing information about the projects and about the company, they will be far more

likely to understand their contribution to the big objectives. This practice provides great help in motivating people: Humans, as shown by religions, feel the need to be part of greater plans and have higher purposes.

Tip 4: Responsibility

Another sudden change for those who become leaders is the scope of their responsibility. Before being in a leadership position, each individual is accountable for his or her work alone. This is obviously different for leaders. Still, there are not so obvious changes worth mentioning.

A typical situation which exposes these differences is the case when the newly appointed leader is confronted by his or her boss regarding some issue on the project. Any good leader will understand who was responsible for the part which had issues. The sometimes the counterintuitive part is deciding on how to proceed from this point.

Many beginner leaders will, sometimes in the human act of self-preservation, explain to their bosses that the issues are coming from a specific team member (Stone et al. 2000). This is an inappropriate approach.

The leader is responsible for the results, regardless of the circumstances. The leader should take responsibility for the current state of the project at all times. If a team member is underperforming, it is the responsibility of the leader to deal with it before it becomes a problem to the project.

Moreover, in the cases where the leader doesn't have the appropriate people or resources to handle a task, it is his or her responsibility to inform it to the boss as soon as this information becomes available.

Tip 5: Sincerity

One of the most important traits of a leader is sincerity. The people working with a leader are intelligent adults. More often than not, the team members will notice when the leader is not being sincere.

More than just noticing, people will first try to understand why the leader is being insincere. And often they will pay back behaving the same way: being insincere as well. This is not the trust environment expected from the successful teams.

Some new leaders sometimes will consider they have good reasons to be less than sincere with their teams. Sometimes they actually want to protect them from criticism from other people or teams; other times there are bad news such as possible layoffs ahead and the leaders don't want the team to lose focus. Still, a leader should understand that if he or she can cope with it, so do the team members.

As intelligent adults, they most likely faced bad news before (Stone et al. 2000). Most of them had a broken heart; most of them heard of people dear to them dying: This certainly dwarfs any bad news a job in the game industry can bring. Going further, when presented with difficulties those people may help in finding good solutions to it or, when not possible, either start coping with the issue or accepting the loss.

Still, a caring leader will have concerns about how a person will feel after criticism is delivered. A caring leader won't want to hurt people's feelings or self-esteem. He or she will deliver the criticism making it clear that the problem is not the person, but the action, behavior, or result achieved.

Tip 6: Trust

Trust is an absolute key element when working with people (Sinek 2009). It is one of the foundations of human society: When humanity was young, threat was all around. There were no cities where you could be safely away from predators. Carnivores such as wolves, bears, and big felines were a common threat. Sleeping was particularly dangerous for humans in the wild.

Survival required cooperation (Sinek 2009). There had to be people awake during the night to alert the others of possible attacks, and the lives of the entire group would depend on these people doing their jobs. The group had to trust them completely and reciprocate, or else this equilibrium would eventually fail.

This was the reality of the human race for a period far longer than recorded history up until when this text was written for the first time. This is not just a fad, a modern behavior; this is something so old that it is likely even recorded in human genes: Humans are programmed to cooperate with each other, but this cooperation requires trust.

Let's now take these ideas what most would consider a somewhat safer environment: the office of a game studio. The central idea remains: A good leader should understand that if he or she wants to be trusted, the first thing to be done is to trust the people with whom he or she works.

And what does trusting someone mean? It means primarily that the leader will delegate work as one of his or her main activities. Moreover, this should be done trusting that the people receiving the tasks will be able to accomplish them well. Also, just like a loving parent, a leader, especially if he or she is a good engineer, should understand that it's time for the team members to shine and his or her to support it.

A natural consequence of this line of reasoning is the inherent absurdity of micromanagement. It not only simply doesn't work with engineers but also increases turnover. Micromanagement screams out loud: "I don't trust you can do your work well and on time." Any leader seeking trust must absolutely forget micromanagement.

Returning to the concept of reciprocity, for a leader to have team members who will answer honestly, the leader should first answer honestly. If a leader wants the team members to take risks, the leader should be the first to take those risks and take them for the sake of the team.

For example, if the leader disagrees with some decision, he or she should state so while reminding that still his or her role is to uphold this decision. The team members will reciprocate up to the point they believe a leader will go for them, and they will just believe by seeing the leader to it first.

There are, also, situations when a team member loses the trust of the leader. If this happens, action should be taken by the leader. Often involving the team on deciding which action to take is a good option. A leader trying to dodge this kind of problem will pass a message that there are no consequences to breaking the trust, which can potentially undermine the trust of the entire team.

Tip 7: Vulnerability

A common issue new leaders have, especially those who were excellent doers, is dealing with their own vulnerabilities. In the game industry, often a doer is evaluated by his or her individual capacity to generate code or assets. Leaders, on the other hand, are not evaluated only by their individuality: for this reason, even the best of the professionals or the most self-demanding one will inevitably have vulnerabilities, even if they come from one of the team members.

Still, it's far more usual for leaders to have their own vulnerabilities (Brown 2010). A common one for the newly hired or promoted is not being acknowledged as a leader by the team or some of the team members, usually the most senior ones. Another usual vulnerability is being simply less technically knowledgeable, if at all, than the team members.

It is of vital importance for the leader to correctly access the situation he or she is in and understand his or her vulnerabilities. More specifically, a leader should understand what he or she cannot do.

Either facing a limitation or struggling to avoid mistakes, the key element to take away is asking for help. The leader is not expected to know it all; he or she is not expected to be a super programmer or super artist. The leader is not expected to be able to solve all problems from a team. The leader is expected to care for the team and for the goals, and having help from others is the best way to do it.

A good way for a leader to access if he or she is doing properly on this topic is the feeling of being a fraud. A leader who feels he or she is a fraud is much more likely to access his or her vulnerabilities correctly. As the philosopher Socrates said: "All I know is that I know nothing."

Feeling as a fraud, of course, is not a necessary condition. But it's easy to feel like one when doing right. A good leader should not only care for his or

her team members to achieve their goals and, just as importantly, strive to grow the team members into becoming independent of him or her.

Having a team independent of the leader leads into his or her mind the natural questioning of how much he or she is needed by the company. Having this question in mind, while being well regarded by his or her peers or being able to repeatedly grow independent teams (just like being able to raise independent children), is a great sign for a leader.

Tip 8: Challenge

While a leader must inherently trust his or her team members, it is critical for the job to ascertain the right problems are being solved (Acton 2014). A common tool for this task is periodically checking what a team member is doing and challenging tasks when planning for them.

In order to maximize the chance of the priorities and plans being right, the leader can use a very important tool: asking questions (aka challenge). There are two main questions: What problem do we want to solve with a given task and why are we solving this problem?

While both questions are important, the "why" question is by far more relevant: a bad answer to a "why" might indicate that performing a given task is plain senseless. Going further, it happens quite often that questions in game development have several layers of complexity: to reach the primary reason why some tasks are required may need a series of "whys" asked on top of each other's contexts.

The idea behind this analysis is similar to the Socratic philosophy. Asking sufficient "whys" is a good way to understand where one knowledge ends and beliefs begin.

There is a risk into this approach, though: reaching a wrong conclusion. A reason for this to happen is that proving a decision is based on a belief makes it easy for someone to discredit an argument as most people want to make decisions seemingly based on reason.

Still, it's likely that most people will not apply the same technique on possible counterarguments. Also there is a good chance that the people the leader is talking to, especially if they are engineers, will have poor communication skills meaning that they won't be able to properly articulate the answer to the "whys" leading to an incorrect analysis. Apart from this, sometimes, people, for many reasons, will simply prefer not to verbalize some arguments.

One way to help in avoiding some of the risks of challenging arguments is, when possible, give people time to think about the questioning avoiding taking decisions during the challenging of an argument. This allows people to rethink about the answers they gave and improve their arguments.

The bottom line is: a good leader should challenge tasks and arguments but should understand that winning a discussion doesn't make the winner's ideas correct.

Tip 9: Commitment

Commitment is a key element in successful game projects (Acton 2014). Committed people tend to deliver work on time and with better quality. More often than not, therefore, successful teams are also committed teams: a good leader should foster this trait.

A key element on this context is having people agree on what should be done and, in many cases, how it should be done. An effective means to achieve it is letting the team decide by itself those two points: it's far easier to convince someone of his or her own ideas than of ideas coming from anyone else.

Obviously there are requirements for this idea to work: the team should be well informed of the sought objectives, it should not be formed only by juniors, and the leader should be ready to challenge the proposed plans. All of those elements, in most environments, are under control of the leader. A positive side effect of it is making them feel useful.

Once the agreement on what and how a plan should be done is reached, the proper scheduling of the tasks is another critical element to achieve commitment. If the team members consider a schedule unreasonable, they are likely to be right and unlikely to commit to it.

To support this argument, the people working in the game industry, no matter who is their leader, are often professionals. Sometimes they are even specialists on their craft. They are most likely better aware of their own capacity than anyone else. Going against it often justifies lack of commitment, as itself is often a lack of common sense.

Still, just planning with the team what should be done, how it should be done, when on time it should be done, and by whom it should be done is not enough to achieve proper commitment. A leader should also be ready to face a dire reality: intermediate steps of plans fail a lot. This often happens quite early in projects.

Delegating responsibilities over a plan's area to an individual or a group is the next step a leader can take into fostering commitment, especially on what regards fail contingency measures. Doing this, even when something unpredicted happens, people will understand who should solve it and the impact it will have on others: their primitive trust mechanism is more likely to trigger, generating commitment.

On the other hand, if plans are given to the team instead, they are much more likely to disagree upon its feasibility. People will feel forced instead of committed.

Tip 10: Vision

One of the important parts of the human mind is the desire to be part of something big: finding a meaning to a set of actions, something more than just surviving. It's no coincidence that religions can be very appealing: it's a human need.

A good leader should understand this aspect of human nature and help people fulfill their needs. Care should be taken, though, not to abuse it: most game companies won't want their employees blowing themselves, or at least ruining their personal lives, for the sake of their game.

The way for a good leader to work this aspect out is providing his or her team with the grand strategic vision behind the companies. In the game industry, the term "world domination" is often heard. Explaining how the company intends to achieve it and showing each team member's individual contribution for it is a great start. People will understand they have a future in the company doing so and are likely to stay longer (DeMarco and Lister 1999; Acton 2014).

There are some cases, though, where there is no grand strategy plan behind a company. Sometimes the company is looking for a new identity. It is conceivable to see this happening with one-hit studios, which often have a lot of money but don't know what to do with it. When this happens, an unusual opportunity takes place: the leader and his or her team have the chance to create a grand strategy for the company.

A common element of winning visions inside companies is market disruption. This can happen through new business or monetization models, new technology, inventing a new gameplay genre, finding an undersupplied niche, or reaching out for people who weren't previously gamers.

A good leader, therefore, should be ready to provide his or her team with the company vision. If none exists, he or she should create one.

Tip 11: Self-Improvement

Reality is simple: no one is perfect. Accept it.

The consequence of this affirmation is that all leaders can improve. A good one, therefore, should always work on improving himself or herself (Acton 2014).

There are several means to achieve self-improvement. A good leader will often try a few of them at a time. Still, among all the possibilities, one of them is mandatory: firsthand experience. Rarely anything will yield a deeper result than actually facing a challenge. Luckily this usually comes naturally as part of a leader's job; when it doesn't, though, this should be regarded as a warning sign and could be a reason to change jobs.

Most of the other means to achieve self-improvement gravitate around the sharing of experiences. Talking to other leaders and reading leadership-related texts can give the leader ideas about what to try when facing the challenges of this job.

Another category of actions is presenting one's experience. Once a leader finds him or her in a role

where he or she is expected to present his or her accumulated knowledge about leadership, this can be turned into an exceptional opportunity: change empiric information into systematic solidified knowledge.

Apart from that, a good leader should always be ready to listen. Sometimes all that is needed to solve a problem is a person in a different mind-set: a good leader will understand this and be happy to expand his or her own mind-set whenever confronted with a different one. Listening is a key element for it.

A good leader should also understand that he or she is often dealing with incomplete information, especially when it regards people. The result of it is that decisions which may seem obviously right can be the very opposite. Listening to people, especially the team members, is, therefore, a crucial element for improving a leader's capacity when regarding specific teams.

Finally, even more important for a leader than his or her own self-improvement is fostering this value for the team he or she leads. A good leader should not only be able to create a self-sufficient team but also a team capable of improving itself over time.

Tip 12: Yourself

Being a leader is hard. A leader is expected to always put the needs of the team above his or hers. This can be very taxing, as there is a single person having to care for many, having to worry about the results of many, having to worry even if their life outside work is going well.

A common mistake novice leaders do is succumbing to the sheer amount of things to care for and start having an unbalanced life. This is particularly true for the work/life balance.

The problem of this approach is that the less a person has a life outside work, the less this person will come refreshed to the office. This is a usual way through which stress builds up, and in the game industry this can be often perceived on crunch periods, particularly the longer ones.

When under stress, especially over longer periods of time, people tend to make poorer decisions. They tend to be less tolerant, be irritated over small things, and often overreacting. In the work environment, due to the power relations between the leader and the team, this can be disastrous. A good leader must always control his or her emotions. Emotional stability inspires trust on the people you lead.

It's, therefore, much easier to be a good leader when in a good state of mind. This requires the leader to take care of himself or herself. A happy leader is much more likely to be a good leader, and having a life outside work can be of great benefit for it.

Moreover, a great leader should go beyond merely the work/life balance. Having good relationships outside work is of immense help. This means that many of the things applied to be the leader of a team should apply to the people outside the office.

Above all, love should guide the relationships outside work with other people. Conflicts should be faced and resolved through communication (Stone et al. 2000), instead of endured.

There should be no fear in sincerely showing vulnerability (Brown 2010): trust people, but be ready to challenge any and all beliefs. Commit to goals and to other people, and be accountable for it (Acton 2014). Do so with a vision of yourself. And always seek self-improvement.

In the end life is complicated because we are always dealing with people: the same thing leaders have to deal with every day in their work.

Synonyms

2D Game Engines; 3D Game Engines; Particle system; Physics engine

Definitions

A game engine is a software package designed to simplify and accelerate game development. Game engines provide low-level functionality such as graphics rendering, game physics, and communication with input devices. This allows developers to focus on the actual content of the game: game logic, levels, and assets.

Overview

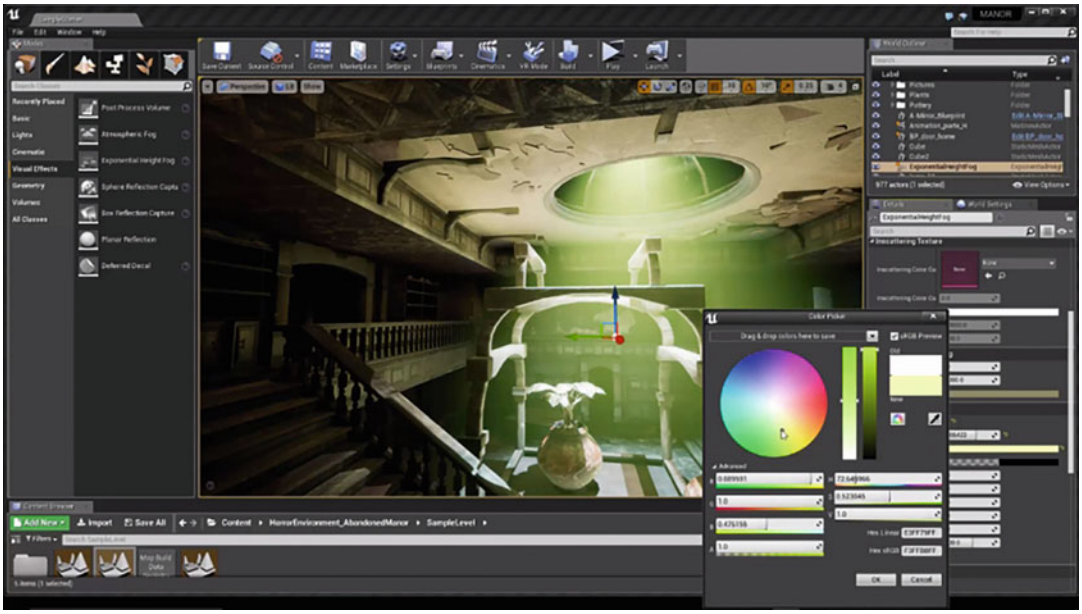
Game engines are based on the idea that a video game can be separated into two discrete layers: low-level "core" functionality and the "content" of the game proper, which, although built on top of the core, is essentially independent (Gregory 2009: 11–13). The "core" comprises basic operations which are indispensable to the game but do not directly constitute it, such as graphics rendering and sound playback, collision checking and in-game physics calculations, memory management and file operations, and so on. Delegating these stock routines to the game engine dramatically improves the efficiency of the development process, enabling the developer to focus on the manifest content of the game, such as, for example, its user interface, level design and physics of the game world, game logic and game mechanics, control scheme, etc. (Bishop et al. 1998).

A single game engine can also be reused in an indefinite number of games, which further streamlines the development process. Additionally, many modern game engines support multiple platforms, making it possible, for example, to use the same codebase to create a product for the personal computer, a game console, and mobile devices with minimal modifications.

Commercial-grade game engines are often geared toward a specific type of game. For example, id Software's *idTech* series of engines are specifically designed for use in first-person shooter games such as *Doom* (2016) and *Rage* (2011), while Telltale Games' eponymous *Telltale Tool* is intended for choice-driven adventure games with quick-time events. Engine specialization helps optimize resources and perfect the implementation of the particular features relevant for a given type of game: for example, skill trees and inventory management for role-playing games or graphics–audio synchronization for rhythm games. It also means that the choice of a game engine is a crucial decision: while the engine's workings may not be visible to the player, game engines can, through their functionality, "regulate individual videogames' artistic, cultural, and narrative expression".

Recent years, however, have seen a rise to popularity of more universal game engines such as *Unity* and *Unreal Engine*, whose functional range has gradually increased to the point where they can power most types of games. Even so, each game engine has its own set of characteristics and may be more or less suitable for particular tasks. For example, of the two engines mentioned above, *Unreal Engine* has more advanced graphical capabilities, while *Unity* is less computationally expensive and supports more platforms (Dickson et al. 2017).

While the term "game engine" in a narrow sense only designates a software infrastructure that powers a video game, many popular engines



Game Engine, Fig. 1 Like many modern game engines, Unreal Engine includes a scene editor and an integrated development environment

bundle with an integrated development environment, allowing developers to code the game in the same software ecosystem where it is tested. It is also common for a game engine to come with a level editor and sometimes a user interface editor, as is the case for *Unreal Engine* and *Torque 3D*. Some game engines, such as *Unity* and *GameMaker*, also support add-ons and plugins, making it possible to extend their out-of-the-box functionality with third-party solutions (Fig. 1).

History

In the early days of gaming, video games were often programmed from scratch (Bishop et al. 1998). However, the increasing complexity of the video game medium, the evolution of software and hardware, and the advent of the multi-million-dollar game industry with its pressure on cost and efficiency have made this approach unsustainable in commercial game development. Code was increasingly recycled and dedicated libraries were created to deal with low-level operations like graphics rendering.

The desire to further optimize the development process eventually led to the emergence of the game engine. One of the earliest examples is Infocom's Z-machine, a virtual computer created in 1979 which executed commands in its own language, specifically tailored for interactive fiction games such as *Zork*. The use of a virtual machine helped Infocom avoid developing separately for the multitude of home computer architectures that were in use at the time (Bartholomew 2008).

In 1984, Sierra On-Line released *King's Quest: Quest for the Crown*, the first game based on Sierra's own *Adventure Game Interpreter* (AGI). Initially, AGI was created because Sierra felt that an easier, tailor-made engine would allow writers and designers to work more independently from programmers, thus benefiting the workflow (Loguidice and Barton 2012: 150). The company ended up using AGI in 14 different adventure games before switching to the more advanced Sierra Creative Interpreter in 1988. By that time,

Game Engine, Fig. 2 Ultima Underworld (1992) was one of the first games based on a 3D game engine

Sierra's competitor *LucasArts* was using its own custom engine SCUMM to create point-and-click adventure games (Black 2012).

The early 1990s oversaw the emergence of 3D game engines. A notable early example is the engine used in *Ultima Underworld* (1992), which was partially based on the basic 3D rendering engine of *Space Rogue* (1989), but was much more advanced, adding the use of texture mapping (Paul et al. 2012). In the same year, id Software released *Wolfenstein 3D*, a pioneering first-person shooter, also powered by an engine from an earlier game (*Hovertank 3D*) with the addition of texture mapping and ray casting. Following the success of *Wolfenstein 3D,* id Software set an important precedent by licensing the game engine to other companies who then produced such titles as *Blake Stone: Aliens of Gold* (1993) and *Super 3D Noah's Ark* (1994). This heralded the era of third-party engine licensing, where the use of an in-house game engine was no longer inevitable. Id Software in particular continued licensing the engines for its subsequent titles such as *Doom* (1993) and *Quake* (1996) to other developers. In addition, first-person shooters' growing popularity demanded increasing technological innovation, with each major title expected to be more advanced than the previous one, thus necessitating a more sophisticated engine. As a result, first-person shooters "played a fundamental role in founding the industry of game engines" in the 1990s (Fig. 2).

Another significant development was the emergence of consumer-grade game engines, aimed at hobbyist game creators with little expertise in programming. Clickteam's *Klik & Play*, released in 1994, was an important early game engine which was easy to use, had an integrated event and level editor, and relied on solely visual coding (Djaouti et al. 2010). It was followed by other engines, such as *GameMaker* and *Construct*, as well as technologies such as

Game Engine, Fig. 3 Klik & Play (1994) was a pioneering consumer-grade game engine

Macromedia Flash, which have empowered enthusiasts with little technical knowledge to make their own games (Fig. 3).

Conclusion

Game engines have changed the logic of video game development, introducing a more efficient, content-centered approach and simplifying the production of multiplatform content. The appearance of consumer-grade engines and the easy availability of professional solutions such as *Unity* and *Unreal Engine*, coupled with the advent of Web 2.0, has also significantly lowered the entry barrier to game development. Despite some popular engines positioning themselves as universal, the choice of an engine is still a crucial decision which can have much influence on the development process and its outcome.

Game Interface: Influence of Diegese Theory on the User Experience

Isabel Cristina Siqueira da Silva and Felipe Oviedo Frosi
UniRitter Laureate International Universities, Porto Alegre, Brazil

Synonyms

Diegetic interfaces; Graphical interface; HUD (heads-up display); Human-computer interaction

Definitions

User experience (UX) is the set of elements and factors related to the interaction of the user with a particular product, system, or service whose result generates a positive or negative perception.

The game interface is fundamental for the player experience once transmits information such as life and/or power bars, stopwatches, inventory, punctuation, etc. This information is referenced by heads-up display (HUDs).

Diegese refers to the world in which the events of a story occur, defining what makes or does not part of the virtual scenario and what is visible to the characters that inhabit this alternative universe.

Introduction

The user experience (UX) is the set of elements and factors related to the user interaction with a particular product, system, or service whose result generates a positive or negative perception. When

interacting with a product, people seek new experiences through perceptions that involve practical and subjective aspects such as usability, efficiency, and satisfaction. Beyond subjective, UX is dynamic since changes over time due to the presentation of new challenges and rewards (Hassenzahl and Tractinsky 2006; Schell 2008; Garrett 2010; ISO 9241-210, 2010; Costa and Nakamura 2015).

According to Russell (2011), the interface design is often one of the most challenging aspects of game design. This fact occurs because there is a great amount of information to transmit to the player in relation to the screen space available. If this relationship is not balanced correctly, the user experience with the game can be frustrating. Other elements that also directly influence the perception of the interface by the user are color and composition concepts (Ware 2008).

Game interfaces are usually composed of two main elements: (1) controls common to other computer systems, such as buttons and menus and (2) heads-up display (HUD), which refer to graphic elements present on the game interface that transmit information to the user. The integration of the HUD components and the game world influence the immersion of the user experience and interaction.

In this sense, the HUDs can be displayed in a traditional way or incorporated into the universe of the game, in order to offer immersion to the player and, consequently, a more concrete experience. In this sense, a rereading of the diegese theory can be done for the definition of HUDs, breaking with traditional paradigms of graphical interfaces in games. Two main aspects are part of the theory of diegese: the narrative and the fourth wall (Genette 1980; Rohden et al. 2011).

This entry discusses concepts of diegese theory in the scope of design and development of graphical interfaces for games. We relate the elements of the narrative and the fourth wall to the experience provided to the player, comparing the different forms of HUD presentation during the evolution of digital games. Diegetic and nondiegetic elements, especially in HUD, are discussed in order to clarify how these relate to the transposition of the fourth wall as a strategy to achieve the projected user experience.

The text is organized as follows. Section "Games and Diegese Theory" addresses the main issues related to diegese applied to the game interfaces. Section "Applying Diegetic and Nondiegetic Interfaces in the Game Design" presents a discussion of the concepts presented in section "Games and Diegese Theory," and finally, section "Conclusions" presents the final considerations.

Games and Diegese Theory

Considering the user experience in games, the graphical interface should be constructed in order to provide the communication between gameplay objects and the player. Among different studies involving games interaction, Fagerholt and Lorentzon (2009) suggest the use of diegese theory, adapted from the areas of literature, cinema, and theater.

In game design area, the diegese refers to the game universe, defining what is or is not part of the virtual world, and is based on two main principles: the narrative and the fourth wall. The narrative is related to the game story (fictitious world). Besides, the fourth wall deals with the imaginary division between the player and the game world. For the player to immerse himself in the game world, he must pass through the fourth wall.

The player's ability to move between the real world and the game world depends on how the interface designer provides information for him. In this sense, the HUD elements are considered diegetic if they are part of the universe of the game and the characters are aware of these elements. Thus, the HUDs must communicate something understandable to the characters according to events and rules defined in the universe. In some cases, the characters will interact directly with these elements and, eventually, these can exist exclusively to communicate something, not being functional.

The game Dead Space (Electronic Arts Inc. 2018a) is an example that employs the

Game Interface: Influence of Diegese Theory on the User Experience, Fig. 1 Dead Space game (Electronic Arts Inc. 2018a)

concept of diegetic interface. As shown in Fig. 1, attached to the character's armor is a luminous marker that represents his life bar. This element visibly is part of the universe of the game, being present along with the main character, that is, it is not an element that only the player can visualize, but any character of the game universe.

The integration of diegetic elements into the game universe is considerably relevant to creating the projected experience – not only in relation to the interface but also to the game in general. If a diegetic element escapes the context of the universe, this can generate a noise (Schell, 2008) in the player's experience, which potentiates the opposite effect in relation to the goal of diegese in games, which is to increase the immersion and quality of the experience. Thus, diegetic interfaces require a work of harmonization with the elements of the game, in order to transpose the fourth wall in the proper way (Rohden 2011; Russel et al. 2011).

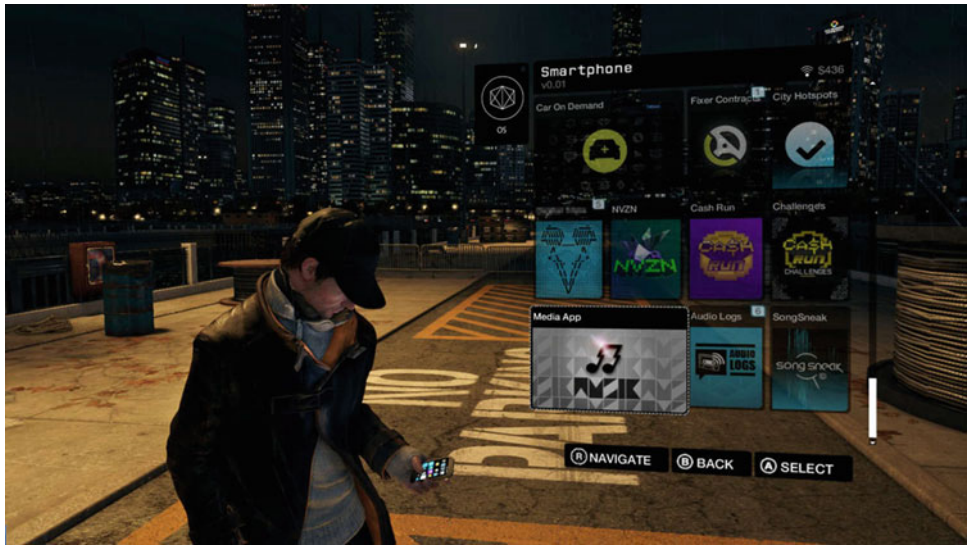
Unlike diegese theory, nondiegetic interfaces are defined as being outside the game universe. The use of nondiegetic HUDs was initially recurrent in the gaming industry and this fact led in some cases to an increase in the insertion of graphic elements, polluting the game interface (Fig. 2). This practice contradicting the idea that only the essential elements should be displayed in an interface (Hassenzahl and Tractinsky 2006; ISO 9241–210 2010; Garrett, 2010). With game industry maturity, diegetic interfaces began to gain space.

Besides diegetic and nondiegetic HUDs, Fagerholt and Lorentzon (2009) propose two other types: spatial and meta. The concept of spatial HUDs is applied when a certain element is present in the 3D space of the game, but it is not part of the universe, nor can the characters see it. In general, these interface elements are used to indicate avatars selected or other indicators. In the game The Sims 4, for example, in addition to nondiegetic elements, some elements with the spatial approach are employed. Figure 3 shows a character, positioned to the right in the image, which is accompanied by a spatial interface element (the balloon).

On the other hand, meta elements are part of the game universe but not necessarily in the 3D plane. In general, meta elements are used as applied effects on the game camera, such as blood dripping from being hit by a shot (as well as other types of damage), or effects of rain particles, solar reflection among others. The Watch Dogs game (Ubisoft Entertainment 2017a) is an example of using HUDs meta with the transposition of the elements of the game universe, which causes the fourth wall to be crossed by the player (Fig. 4). Therefore, during the use of the smartphone of the character, the screen is presented to the player as a nondiegetic element.

Game Interface: Influence of Diegese Theory on the User Experience, Fig. 2 NDI HUDs of World of Warcraft game (Blizzard Entertainment, Inc., 2018)

Game Interface: Influence of Diegese Theory on the User Experience, Fig. 3 The Sims game (Electronic Arts Inc. 2018b)



Game Interface: Influence of Diegese Theory on the User Experience, Fig. 4 Watch Dogs game (Ubisoft Entertainment 2017a)

These four types of HUD discussed in this section can be combined to allow an effective immersion of the user in the game universe, enhancing their experience with the game.

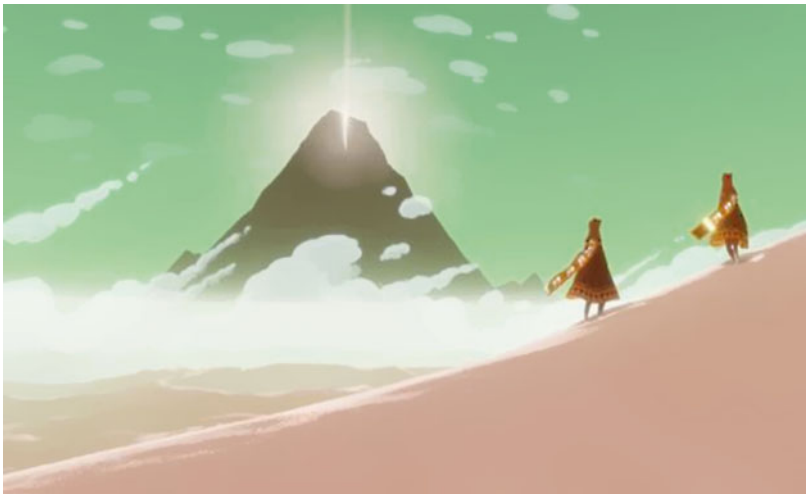
Applying Diegetic and Nondiegetic Interfaces in the Game Design

This section focuses on the discussion of the main aspects related to the design of HUDs in game interfaces based on diegese theory. Thus, some questions that can help the HUD project are listed, seeking to perform a critical analysis situated in the current scenario of games and based on the research carried out in this work:

1. *What are the main advantages of DIs?*
2. *What is the motivation for using DIs?*
3. *Is there any kind of idea that only works in DI?*
4. *Are NDIs still required to achieve the required level of gameplay?*
5. *Can DIs make use of non-diegetic elements in their design?*
6. *What is the tolerance for excess HUDs in NDIs? Is it possible to improve this issue with the free customization of HUDs over the interface?*
7. *Does the game depend on immersion?*
8. *What is the relationship between aesthetics, complexity and gameplay in games?*

Regarding question 1, it is noted that some game genres can improve their immersion with the use of DIs, which help keep the player's attention within the game world. Some games, by their simple nature, do not even need an interface; others, that are not dependent on a large number of mechanics, can use some part of the avatar itself to give feedback to the player, such as the Journey avatars (Sony Computer Entertainment America LLC 2014a; thatgamecompany 2018a, Fig. 5) and the Dead Space avatar armor (Fig. 1), which mask use of a status bar.

Concerning question 2, with the beginning of the popularity of independent games (indie games) in the middle of the seventh generation of consoles, some games present the intention to stand out in a market long structured and dominated by large companies that focused on HUDs based on NDIs. However, the use of DIs represented an innovation, since the use of creativity was the only resource for small gaming companies to gain prominence in this market. Thus, new games, especially so-called art games,



Game Interface: Influence of Diegese Theory on the User Experience, Fig. 5 Journey game (Sony Computer Entertainment America LLC 2014a; thatgamecompany 2018a)

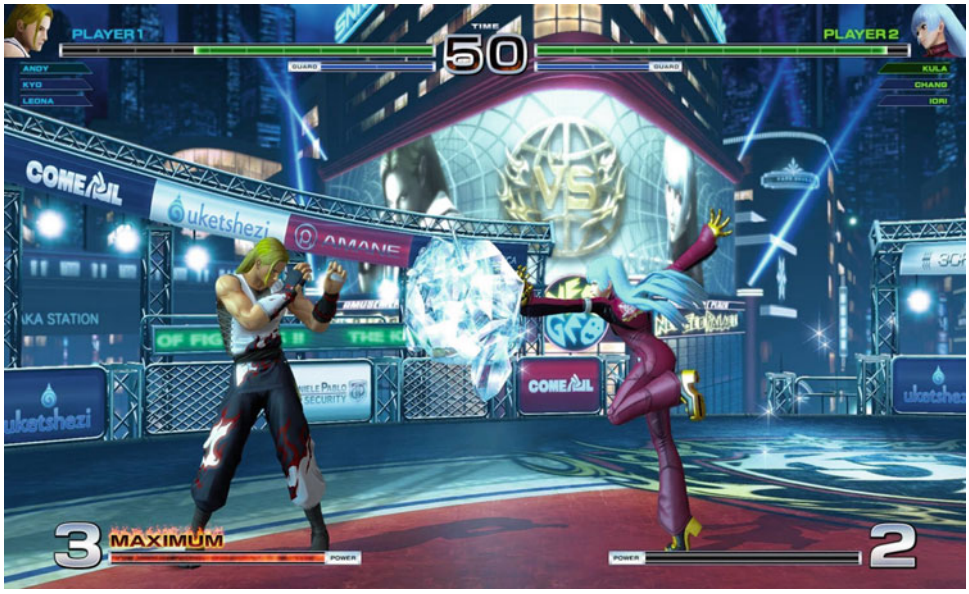
Game Interface: Influence of Diegese Theory on the User Experience, Fig. 6 Flowe game (Sony Computer Entertainment America LLC 2014b; thatgamecompany 2018b)

explore DI integrated in a natural and functional way to game design. The game Flower (Sony Computer Entertainment America LLC 2014b) (thatgamecompany 2018b) (Fig. 6), for example, was one of the first indie games to become popular in the market and to present an innovative interface concept and user experience.

The Journey and Flower games proposals are examples of experiments based on DIs (question 3) and probably would not reach their level of immersion with the use of NDIs. The concepts of these games can only be demonstrated with elements of HUD inserted in the universe, in order to give the player the information and the notion he needs. In this sense, the game Firewatch (Campo Santo, 2018) is another example where the DI is fundamental, because, instead of an NDI with a map containing arrows that aim their objectives, the player has only a map and a compass and must be guided by its own reasoning (Fig. 7).

Regarding question 4, in game genres where the player needs accurate information, usually in numerical form or through bars, NDIs are still the best form of HUD. In the King of Fighters series (SNK Corporation, 2018) (Fig. 8), for example, each millimeter of the bar makes a significant difference for the player to plan attacks on the enemy. In fighting games, hardly an element of identification would be as precise and with communication as clear as the bars of life. One

Game Interface: Influence of Diegese Theory on the User Experience, Fig. 7 Firewatch game (Campo Santo, 2018)



Game Interface: Influence of Diegese Theory on the User Experience, Fig. 8 King of Fighter game (SNK Corporation, 2018)

possibility in this type of game would be to demonstrate how close the character is to being defeated by his body wounds. In fact, several games have used this feature, but it does not meet the need of the life bar. This is an example of how NDI is still needed and cannot always be replaced.

In relation to question 5, the game Dead Space (Fig. 2) can be considered an example of ID that makes use of the style of NDI, incorporating the latter to the universe of the game. For example, status bars and menus are displayed as screens within the game universe in a futuristic way. The Far Cry 2 game (Ubisoft Entertainment 2017b)

Game Interface: Influence of Diegese Theory on the User Experience, Fig. 9 DI presenting information in the form of NDI in Far Cry game (Ubisoft Entertainment 2017b)

(Fig. 9) is another example that mixes concepts of NDIs and DIs on the same screen. Although most HUDs follow the concepts of DIs, information such as ammunition, opportunities for interaction, and health are displayed as a message in the format of NDI on the screen. In the same context, Team Fortress 2 game (Valve Corporation, 2018) presents spatial elements in addition to diegetic and nondiegetic elements (Fig. 10).

Considering question 6, it is observed that the amount of HUDs in NDIs is directly proportional to the game complexity. In some cases, a large amount of HUDs is unavoidable for the desired gameplay, such as the World of Warcraft game (Fig. 2). On the other hand, the possibility of interface customization helps the player to create an identity with the game, allowing the adaptation of the HUD positions according to their needs and preferences (Preece et al., 2005). This feature is especially important when the game interface has many types of HUDs.

The question 7 addresses gameplay versus immersion. In this sense, it must be considered that the focus of the player is on the gameplay. However, gameplay and immersion can go hand in hand in order to enhance the player experience. Aragão (2016), for example, states that the issue of immersion in the fictional environment of the game is inseparable from the gameplay. Some indie games exploit this relationship, breaking conventional paradigms of games through an abstract experience related to exploration and discovery as in the Hohokum game (Sony Computer Entertainment America LLC 2014c; Honeyslug Ltd., 2011) (Fig. 11).

Finally, regarding question 8, it should be considered that it is possible to play a fun game with an underdeveloped narrative and an unpleasant aesthetic, but it is difficult to play a game with good aesthetics if the experience it offers is not satisfactory. The concept of gameplay, however, is extensive and even a game that offers little complexity does not necessarily become an inferior game. Such games can abdicate the complexity for a game that focuses on aesthetics, as long as the gameplay does not suffer any kind of commitment. Sound Shapes game (Sony Computer Entertainment America LLC 2012, Fig. 12) is an example that had significant success in the gaming industry.

After analyzing the eight questions raised in this section, is noticed the type of HUD to be employed in a game depends on some key elements:

- Player/user experience
- Immersion level
- Narrative

Game Interface: Influence of Diegese Theory on the User Experience,

Fig. 10 Team Fortress 2 game (Valve Corporation, 2018): (**a**) Spatial elements; (**b**) diegetic and nondiegetic HUDs

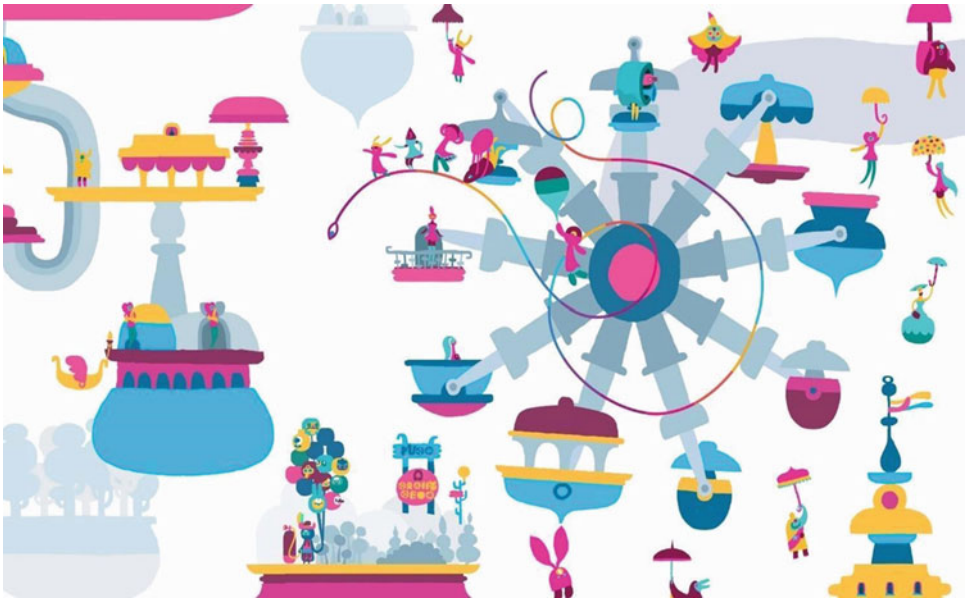
- Aesthetics
- Style
- Target audience
- Complexity of mechanics
- Feedback

Issues related to the definition of DI or NDI should take into account these listed aspects, since the gameplay and usability depends on the level of accuracy of the information related to the mechanics of the game. Moreover, some studies have been carried out in order to analyze the preference of users for diegetic or nondiegetic interfaces as well as to assess the accuracy of diegese design for games (Fagerholt and Lorentzon 2009; Iacovides et al. 2015; Peacocke et al. 2015). Is noticed that diegetic interfaces positively impact the user experience, increasing immersion, cognitive involvement, and a sense of control. However, the user experience also depends on the player's level of expertise and game genre.

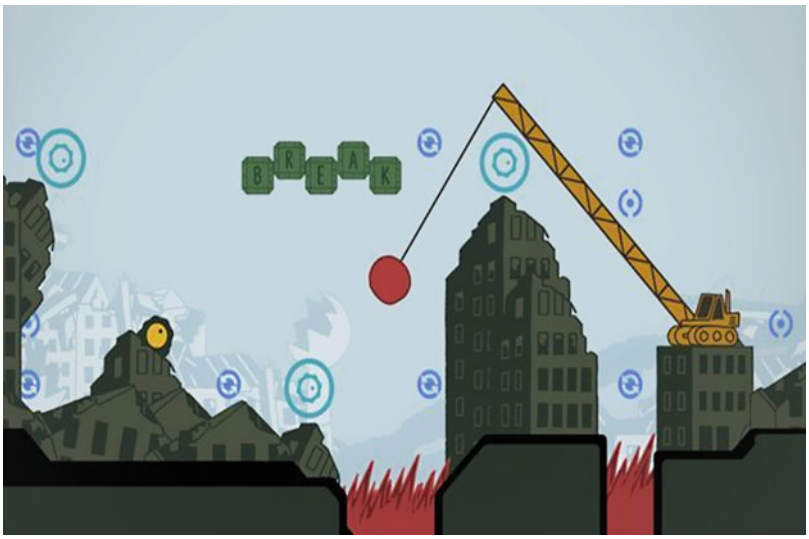
Conclusions

The evolution of the gameplay changes the way the player interacts with the game, having different forms of HUDs and feedbacks. Most games with diegetic interface end up being natural enough that the player does not realize that he crossed the whole adventure without using a conventional nondiegetic interface. On the other hand, the increasing complexity of the games is directly related to the demand for nondiegetic interfaces, due to their greater precision in the display of information.

The understanding of the diegetic and nondiegetic interfaces presented in this work can



Game Interface: Influence of Diegese Theory on the User Experience, Fig. 11 Honokum game (Sony Computer Entertainment America LLC 2014c; Honeyslug Ltd., 2011)



Game Interface: Influence of Diegese Theory on the User Experience, Fig. 12 Sound Shapes game (Sony Computer Entertainment America LLC 2012)

collaborate for the best quality in interfaces design. However, there is no interface approach that will always be the most appropriate, just as in some cases the combination of different approaches can foster the construction of a more consistent HUD.

Game Loop and Typical Implementation

Aaron Hitchcock and Kelvin Sung

Synonyms

Game engine loop; Game engine main loop; Game engine update loop

Definitions

At the innermost core of every game engine is a compact infinite loop. This loop continuously iterates through the steps of receiving and processing player input, updating the entire game state, and rendering and displaying the game objects. This loop is executed at a short but discretised time interval supporting seemingly instantaneous interactions between the players' input and the graphical gaming elements. This constantly running loop is referred to as the game loop.

Introduction

To convey a lifelike sense of instantaneity, each cycle of the game loop must be completed within a normal human's reaction time. This is often referred to as real time: the amount of time that is too short for humans to perceive both visually and cognitively. Typically, real-time can be achieved when the game loop is running at a rate of at least 40–60 cycles in a second. The speed of a standard game loop, with one drawing operation per cycle, can be quantified as the number of drawn frames per second (FPS), commonly called the frame rate.

An FPS of 60 is a good target for performance. At such a frame rate, update of the screen will coincide with a game update. This synchronicity increases the fluidity of motion and reduces the perception of the graphics lagging or appearing jittery. This is to say, your game must receive player input, update the game world, and then draw the visual elements of the game world all within 1/60th of a second.

The game loop itself, including the implementation details, is one of the most fundamental control structures of a video game. With the main goal of maintaining real-time performance, the details of a game loop's operation are of no concern to the rest of the game. For this reason, the implementation of a game loop should be tightly encapsulated in the core of the video game with its details hidden from other operations and gaming elements.

Typical Game Loop Implementation

A game loop is the mechanism through which the in-game logic and drawing of visible elements are continuously executed and presented. A simple game loop consists of processing the input, updating the state of game objects, and drawing those objects, as illustrated in the following pseudocode:

```
initialize();
    // Initialize the game state
while(game running) {
  input();
       // Receive input from the user
  update();
       // Iterate through and update
          every game object
  draw();
       // Render and display all visual
          elements
}
```

As discussed, an FPS of 60 is required to maintain the sense of real-time interactivity. When the game complexity increases, one problem that may arise is that sometimes a single loop can take longer than 1/60th of a second to complete. When this happens, a game would have to run at a reduced frame rate and the entire game will appear to slow down. A common solution is to prioritize which operations to emphasize and which to skip. Because correct input and updates are required for a game to function as designed, the draw operation is often the one that is skipped when necessary. This is known as frame skipping, and the following pseudocode illustrates one such implementation:

```
elapsedTime = now;
    // Time for one loop cycle
previousLoop = now;
    // Begin of previous cycle
while(game running) {
    elapsedTime += now - previousLoop;
       // Time for previous cycle
    previousLoop = now;

    input();
       // Receive player input
    while( elapsedTime >=
      UPDATE_INTERVAL ) {
```

```
        // if previous cycle took too
           much time
        update();
            // Ensure game is up to date
        elapsedTime -= UPDATE_INTERVAL;
    }
    draw(); // Draw the updated game
}
```

In the pseudocode above: UPDATE_INTERVAL is the maximum time allowed for one game loop cycle. When the elapsed time between completed game loop cycles is greater than the UPDATE_INTERVAL, the update() function will be continuously called until the actual game state is caught up. This means that the input() and draw() operations are essentially skipped when the game loop is running too slowly. When this happens, the entire game will appear to run slowly, with lagging player input responses and frames skipped. However, the game logic and state will continue to be correct.

Notice that the while loop that encompasses the update() function call simulates a fixed update time step of UPDATE_INTERVAL. This fixed time step update allows for a straightforward implementation in maintaining a deterministic game state.

Game physics system; Game physics; Physics engine; Rigid body physics

Definitions

A game physics engine is a self-contained subsystem of a game engine which defines the physical characteristics of objects in the game world. The subsystem is typically utilized to simulate and approximate lifelike interactions between game

objects. A game physics engine may not be present in all game engines, but when one is defined, it operates on simple geometric shapes and is only invoked when necessary. This is because the simulation of physical interactions is computationally costly and typically only a selective subset of objects in the game world would define physics components and participate in the simulation.

Introduction

Game object interactions that mimic real life have become a key element of many modern PC and console games as well as, more recently, browser and smartphone games. For example, when shooting a basketball in a video game, the player would expect the ball's trajectory and interactions with the backboard and hoop to resemble the physical world. An effective way of conveying real world object behaviors is by approximating and simulating the underlying physics based on a game physics engine subsystem.

A Rigid Body Game Physics Engine

The range of topics within physics for games is broad and includes, but is not limited to, areas such as rigid body, soft body, fluid, and particles. Rigid bodies are objects that do not change shape. For example: a Lego block, your desk, or the hardwood floor. The interactions between rigid bodies, for example, a falling Lego block bouncing off your desk and landing on the hardwood floor, are best understood scientifically and thus most straightforward to simulate computationally.

Rigid body simulation approximates many types of object interactions in video games and is the core of most game physics engines. A rigid body game physics engine defines rigid shapes to serve as the components of objects in the game world. At runtime, during each game loop update cycle, the game physics engine would iterate through all defined rigid shapes and:

1. Calculate the motion of the shapes and move them
2. Detect collisions between the shapes, if present
3. Resolve potential interpenetrations between the colliding shapes
4. Compute proper responses for the colliding shapes

The proper implementation of these simulation steps enables believable scenarios when objects physically interact with each other in the game world.

Efficiency Considerations

The computation involved in detecting and resolving collisions between arbitrary rigid shapes can be algorithmically complicated and computationally costly. Most rigid body game physics engine implements two optimizations to address these challenges: *simple shape approximation* and *selective computation*.

Simple shape approximation. Rigid body simulations are typically based on a limited set of simple geometric shapes. For example: rigid spheres, rectangular boxes, and cylinders. In most game engines, these simple rigid shapes can be attached to geometrically complex game objects for approximating their physical behaviors. For example, attaching rigid spheres on the hands of a basketball shooter and using the rigid body physics simulation of the rigid spheres to approximate the physical interactions between the hands and the basketball.

Selective computation. To avoid excessive runtime complexity and resource demands, physics simulation are only carried out for essential game objects. For the basketball game example, while it may be important to model and simulate the physical interactions between the basketball and the hands of the in-game characters, such computations would be unnecessary between other nonessential objects like the basketball and the heads of the characters. To facilitate the selective invocation of computation on only a designated subset of game objects, physics representation and computation simulation are usually abstracted and structured as an independent subsystem within the game engine.

The Context of Entity-Component-System Pattern

Referencing the entity-component-system (ECS) pattern, all objects in the game world are components with only a selective subset having a corresponding physics component defined. The game physics engine simulation only involves the physics components. It is important to recognize that a physics component only attempts to approximate the physical properties of a game object for interaction purposes and that the component typically cannot be used to represent the game object in general as it lacks fine detail. For example, a rigid sphere may be defined as the physics component of a basketball game object. A more striking example would be the in-game character's hands which are likely to be represented by detailed 3D models while the physics components of these objects may be a collection of simple rigid spheres and cylinders.

Player modeling; Preference modeling

Definition

Game player modeling is the study of computational models to gain an abstracted description of players in games. This description helps to detect, predict, and express the behavior and feelings of players and personalizes games to their preferences.

Introduction

Game player modeling is the study of computational models to gain an abstracted description of players in games. This description helps to detect, predict, and express the behavior and feelings of players and personalizes games to their preferences. These models can be automatically created using computational and artificial intelligence techniques which are often enhanced based on the theories derived from human interaction with the games (Yannakakis et al. 2013). It offers two major benefits. First, it helps in content customization to cover broader range of players with different skill levels and adapt challenges on the fly in response to the player's actions (Bakkes et al. 2012). Second, it works as a form of feedback for the game developers and designers so that they may add new innovative features to the games as well as develop new games that advance knowledge, synthesize experience, and escalate the interest of the player (Yannakakis et al. 2013).

The very first instance of research on player modeling was reported in the 1970s where Slagle

and Dixon attempted to model the behavior of opponent players in the domain of classical games by assuming the elementary fallibility of the opponent (Slagle and Dixon 1970). Later on, a search method based on knowledge about opponent players (i.e., strengths/weaknesses) was invented in 1993 (Carmel et al. 1993). In 2000, Donkers improved opponent modeling by taking into account the computer player's uncertainty (Donkers 2003). Afterward, an increasing interest developed in the player modeling of modern video games to raise the entertainment factor (Charles and Black 2004). Recently, player modeling has extrapolated its perspective from opponent modeling to a number of other research topics including player satisfaction (Yannakakis 2008), modeling player's preferences (Spronck and Teuling 2010), runtime challenge adaptation (Yannakakis et al. 2013), playing style, and learning effective game strategies (Lockett et al. 2007). A comprehensive history of player modeling is given in (Bakkes et al. 2012).

A player model can have three types of inputs: user data, sensory data, and in-game data (Yannakakis et al. 2013; Martinez and Shichuan 2012). User data includes personal assessment and third-person observation. The negligible limitations of user data are non-relevant data assessments, short-time memory, and player's self-deception (Yannakakis 2012). Sensory data includes data collected from the sensors mounted on the player's body or in the player's surroundings. The most common sensor data includes biometrical (Gunes and Piccardi 2006), physiological (Drachen et al. 2010; Martinez et al. 2013), peripheral (Omar and Ali 2011), and nonverbal natural user interface with the games (Amelynck et al. 2012). However, the sensor's interface with the player faces challenges when it comes to accuracy and performance. In-game data is based on the player's actions taken within the game to infer performance, skills, strategies, behavior, and game contexts including level completion time, mission failure counts, resource utilization, situation handling, and target achievements (Nachbar 2013; Kim et al. 2012; Weber et al. 2011). The big challenge is to interpret the raw data correctly for high-level player modeling using limited amount of data.

Based on the type of the input data, several learning and data mining approaches are used for player modeling as can be seen in Table 1. The effectiveness of the modeling technique based on user data is calculated using demographic/stereotype approaches (Butler et al. 2010). The major challenge in such models is that they are limited to deal with situations where individuals greatly deviate from the average. The sensory data is correlated to the player's behavior, emotions, preferences, cognitive, and affective states (Drachen et al. 2009). Physiological signals are correlated to arousal and valance using Plutchik's emotion wheel and the valence-arousal scale by Russell (1980), facial expressions using continuous, categorical, and active appearance models, speech or psycholinguistic narrations using PERSONAGE, and psychological factors using Big Five model (Lankveld 2013). In-game data features collected during the game play are used to identify or predict the type of the players which can then be further used for personalized component generation or level modifications (Drachen et al. 2009). An overview of input data gathering, modeling approaches, computational analysis, and applications of game player modeling is shown in Fig. 1.

Although a lot of work has been done on the player modeling, several remaining issues need to be addressed. For instance, sensory data-based models lack non-obtrusive data assessment, data reliability, data validity, vigilance recognition, and quick reactivity. User data-based models exhibit low correlation with the data collection time and the particular situation. In-game data-based models are restricted to particular players' personal interests in game, expert level, mood, enthusiasm, and surrounding environment, making it difficult to generalize for all players. However the generalization problem is resolved by continuously comparing and adjusting procedural personal behavior with human behavior and active player modeling (Holmgard et al. 2014; Togelius et al. 2014). Furthermore, hybrid approaches are used to overcome the issues of individual data-based player models (Arapakis et al. 2009;

Game Player Modeling, Table 1 Techniques used for game player modeling based on the input data types

Game Player Modeling, Fig. 1 Inputtypes, modeling approaches, analysis, and applications of game player modeling

Kivikangas et al. 2011; Nogueira et al. 2013a, b). Game player modeling is also experimented in some commercial games (e.g., Tomb Raider, Civilization IV, and Left 4 Dead), but there are still some problems of generalization (Drachen et al. 2009; Spronck and Teuling 2010; Ambinder 2011). Even though player modeling can be generalized, there is still a gap between the player's characteristics within a game and the real world which needs to be bridged in the future research (Holmgard et al. 2014).

Definitions

Game prosumption refers to the process of both production and consumption of computer games rather than focusing on either one (production) or the other (consumption).

Introduction

Concept of prosumption was first introduced by Toffler (1980) as part of his futuristic outlook to the post-industrial age. Kotler (1986) found the idea of involving individuals in the production of the goods and services they consume rather provocative. Yet, it took a while for consumers not to be considered as passive responders but active creative actors contributing to the value creating process (Xie et al. 2008).

Key Principles and Concepts

In its contemporary use, prosumption implies that consumer participate in the production of the goods that they consume (Ritzer and Jurgenson 2010). Accordingly, presumption involves more than just a single act. It is an integration of participatory physical, mental, and/or social actions in the process of creating desired products. These roles of consumer and producer blended and blurred even more with the introduction of digital media (Pathak-Shelat 2014).

Digital Prosumption

In the digital and online world, prosumption actions are not necessarily solely physical, but may also be virtual. Digital technologies provided more opportunity and visibility to consumer's input in various design, manufacturing, and distribution dimensions of prosumption (Rayna and Striukova 2016). The emerging network economy enabled further prosumption possibilities for market participants and consumers alike (Grün et al. 2011). Individuals, on the other hand, not always wanted to engage in co-creation by contributing their valuable time. Indeed, some argued that vast majority were happy to be only passive consumers at the lack of incentives (Haque 2010). However, games provided the much-needed incentive.

Contemporary Computer Game Prosumption

Most computer gaming experience involves the gamer's engagement in the production of an episode of game play, which is then simultaneously consumed (Harwood 2011). Gaming itself is a prosumption activity. Furthermore, gamers consuming multi-player e-games not only buy and play but also observe other players actions. This collective action produced is then called a virtual game. The integrated experience of online play containing labor during virtual gaming is also referred as *playbor* (Kücklich 2005; Ritzer 2014; Schott 2010).

Examples

There are some players who choose to dedicate an extra effort to modify the games they play, such as the creators of Counter-Strike, Minh Le, and Jess Cliffe (Kücklich 2005). With the advent of highly profitable sandbox games, more players are introduced to prosumption of their own story as they interact with the game world, decide for themselves what they want to play.

Definitions

Game thinking (or gamification) is related to game-oriented thinking, in processes that are not games, aiming to reach a specific objective and using engagement mechanisms.

Game design thinking is focused on the design and development of games based on design thinking methodology.

Introduction

The concepts of game thinking (or gamification) and game design thinking are commonly mixed, although both have different proposals and

Game Thinking X Game Design Thinking, Fig. 1 Gamification or game thinking process (Reproduced from Manrique 2013)

applications (Deterding et al. 2011; Castro 2013; Jewell 2016; Sailer et al. 2017). Marczewski (2014) performed an analysis involving the main differences between game design and game thinking and points out that, while the game design is related to something that entertains people in a fun way, the game thinking proposal is to do something in order to achieve a specific goal.

The term game thinking relates to the use of game elements in contexts that do not necessarily consist of games and/or digital media resources (Currier 2008; Alves 2008). Paffrath and Cassol (2014) argue that game thinking is related to understand different aspects of human psychology, such as the mechanisms of personal motivation and the concept of fun.

Game design, on the other hand, explores mechanics and gameplay, among other things, to make the game enjoyable (Silva and Bittencourt 2016). In this sense, game design thinking is a methodology focused on the design and development of games based on adapted concepts of design thinking and that can be developed in a significant way to the process of design and game development (Gestwicki and McNely 2012).

Considering these aspects, this article discusses the main differences between game thinking and game design thinking and presents a methodology proposal for game design based on design thinking and agile and lean project management concepts. We also discuss the results obtained from the application of such methodology in classrooms of undergraduate courses related to the game design.

The text is organized as follows: In addition to this introductory section, section "Game Thinking and Game Design Thinking Methodologies" addresses the main issues related to game thinking and game design thinking. section "Game Design Thinking" presents the game design methodology proposal, and, finally, section "Conclusion" presents the final considerations.

Game Thinking and Game Design Thinking Methodologies

Both game thinking and game design thinking have their own goals. The game thinking focuses on pushing the participant toward their business goal, while the game design thinking explores mechanics and gameplay, to make the game enjoyable, employing design thinking as a game development methodology.

For game thinking, there are different application proposals in the literature (Liu et al. 2011; Werbach and Hunter 2012; Guin et al. 2012; Landers and Landers 2014). These proposals apply some common steps to the game thinking methodology: definition of challenge and goals, identification of target behaviors, players' understanding, and specification of the fun activity. Figure 1, proposed by Manrique (2013), summarizes these steps.

The first step is the definition of the challenge and goals that will drive the game thinking process. In addition, it is necessary to understand the profile of the players in order to plan activities that motivate them. In this context, the definition of fun activities is the core of the gamification process.

On the other hand, in the game design process, formalisms and methodologies are needed in order to optimize, streamline, and professionalize the game development (Hunicke et al. 2004; Bem et al. 2014; Kristiansen and Rasmussen 2014; Jewell 2016). It is noted that the game design still requires specific methodologies, capable of giving developers the understanding of the game development process in a complete way.

Gestwicki and McNely (2012) argue that the adoption of design thinking as a methodology for the game development is adequate because it provides immersive process based on research, bringing academic objectives closer to business environments. In addition to immersion, the generation of ideas, the possibilities prototyping and the selection of solutions are characteristics of design thinking that can be adapted to the game design. According to Vianna et al. (2012), design thinking is originated from the need to seek new paths to innovation from the human-centered approach, where multidisciplinary, collaboration and the tangibilization of thoughts and processes lead to innovative solutions.

However, while the game thinking area presents methodologies that have a common and well-founded basis, the area of game development lacks proven methodologies, which help game designer to think about the creation process of the game. In this sense, the next section presents a proposal of a game design thinking methodology.

Game Design Thinking

The game design is characterized by the constant need for innovation and reinvention in order to meet new audiences, new static, new experiences, and new technologies. The professional who works in the game design must be able to integrate different aspects necessary to the proposal of a game, which has a multidisciplinary nature. In this sense, the area of design thinking has added quality to the game design, since it is an active and user-centered methodology in addition to preaching the culture of innovation. The latter can be considered as the intersection between three common constraints involving design thinking: desirability, feasibility, and feasibility.

This section presents an evolution of our previous methodology for game design based on design thinking (Silva and Bittencourt 2016). The original proposal was adapted in order to following the iterative cycle of refining designs and getting user feedback as proposed by Wagner and Piccoli (2007).

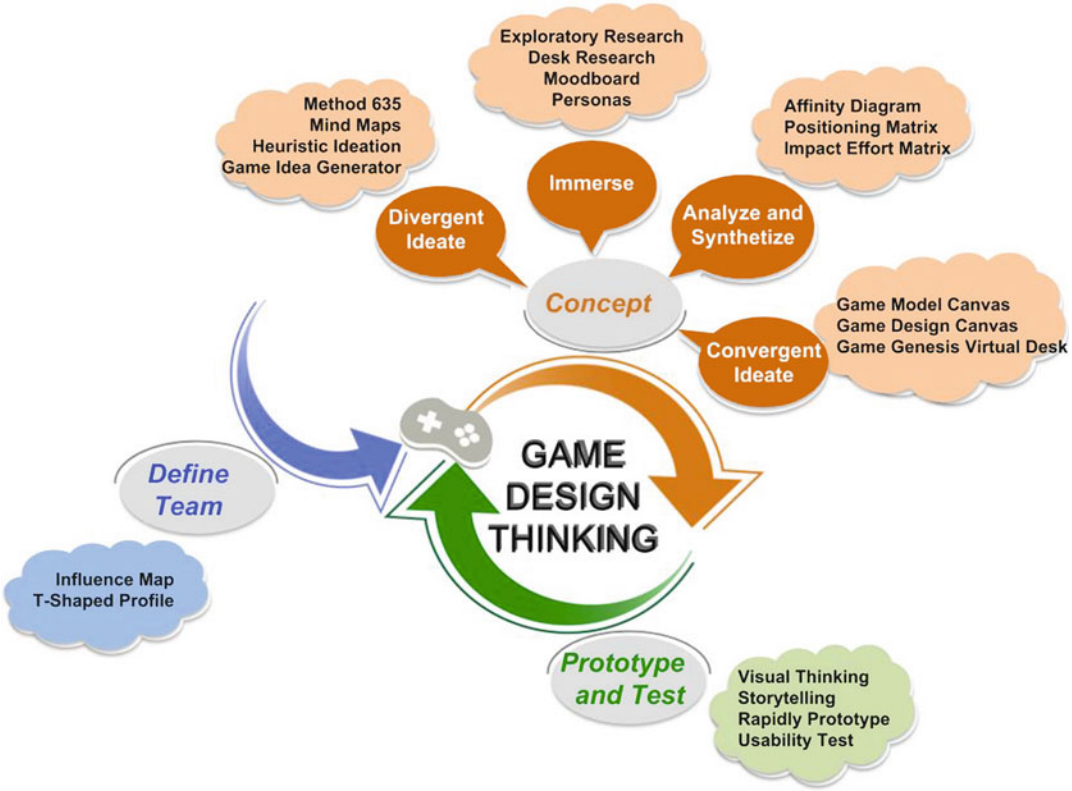
The Methodology

This methodology is divided into four main stages: team definition, conception, prototyping, and validation. As can be seen in the Fig. 2, after the team definition starts, an iterative cycle of conception, prototyping, and tests is realized.

The team definition is a fundamental step to reach the objectives of the game design, due to its interdisciplinary character related to the different stages of conception and prototyping. Team members should interact with each other, identifying opportunities and developing creative and innovative solutions for the game development process. Thus, the team must know each other, focusing on the personality of the members as well as their professional aptitude. For this first stage, two strategies are proposed: influence map and T-shaped profile (Glushko 2008).

In addition to the game objectives, the game conception depends on four basic premises: inspiration, creativity, innovation, and identification of tendencies. Such premises must be present in all phases of conception: divergent ideation, immersion, analysis and synthesis, and convergent ideation. It is noted, therefore, that the conception begins and ends based on the creative process and its two types of thinking: divergent and convergent.

Divergent ideation seeks to create options, from a significant quantity and diversity of ideas, in order to promote different possibilities of game design for the immersion phase. Thus, different brainstorming techniques can be applied, as the method 635 (Rohrbach 1969), the mental map (Buzan and Buzan 2006), the heuristic ideation technique (Gray et al. 2010), and game idea generator tool (Riftpoint Entertainment 2017).



Game Thinking X Game Design Thinking, Fig. 2 Game design thinking (Adapted from Silva and Bittencourt 2016)

After the divergent ideation, the immersion stage identifies the needs and opportunities that will guide the generation of solutions in the next phase of the project. For the game development, four techniques are suggested at this stage: exploratory and desk researches, moodboard, and personas (Vianna et al. 2012; Gray et al. 2010). These tools help in the understanding of the game scenario, through information about the theme of the project from diverse sources (websites, books, journals, blogs, papers among others), and the identification of market niches, with little exploration and potential for expansion.

In the analysis and synthesis step, definitions related to the game must be made. In addition to the data gathered in the exploratory research and the moodboard panel, cards created in the desk search can be arranged in an affinity diagram to identify similarities and patterns between them. Positioning and impact matrices also can be applied at this stage to the definition of criteria such as time, complexity, innovation, costs, team members' abilities, and motivation among others.

The convergent ideation closes the game conception phase and is characterized by making choices based on existing alternatives related to the game. In this step, the ideas generated in the previous steps are critically analyzed and judged so as to select them based on previously defined criteria, expanding the original ideas. In this stage, it is proposed to use two main tools for the convergent ideation of the game: game model canvas (Jimenéz 2013) and game design canvas (Sousa 2014). Another tool that can help the generation of new ideas is the game genesis virtual deck (Gehling 2016). These tools allow the analysis of the game in a systemic, integrated and fast

way, providing insights on how the team should act in order to compose the main idea. It thus helps game developers build, differentiate, and innovate processes, improving their business model to win over the target audience and gain profits.

During prototype and tests, four major actions should be considered: rapidly prototype, publicize/publish the game for feedback and evaluation, feedback analyze, and make improvements if necessary. However, before the prototyping, it is important to align the development process with the team members, and two resources can be used for that: visual thinking (Ware 2008) and storytelling (Rouse 2000). Once the process is clear to team members, the game's implementation begins by choosing technologies that are easily integrated and make it possible to obtain the final designed product.

Finally, the game developed must be published in order to get feedbacks and evaluation of player users. For this, remote and face-to-face usability tests supported by the Likert scale (Likert 1932) are recommended. According to Nielsen (1994), usability comprises five dimensions: learning, memorization, errors, efficiency, and satisfaction/acceptance. Based on the results of testing, the most recent iteration of a game design, changes, and refinements are made, and a new cycle starts.

Case Studies and Results

This methodology was applied in 15 undergraduate courses of different institutions of higher education since 2014. Through an empirical analysis, it can be observed that the methodology of game design thinking allowed groups of students to work in a "free" , focusing on high level concepts.

Thus, as the flow of the methodology progressed, the students had more creative ideas, connecting points not so obvious from the initial premises. The phase of divergent ideation allows the teams an enriching brainstorming, "opening their minds" for the generation of game concepts. In the immersion stage, there is an evolution in the students' original ideas, while the analysis, synthesis, and convergent ideation stages allow the definition of the game concept in an agile and efficient way, summarizing the game design in panels which facilitate the identification of trends, creativity, inspiration, and innovation among team members.

Some groups that started the game design thinking process with a pre-defined concept of their game felt motivated to rethink this. During the prototype stage, the adoption of visual thinking and/or narrative allowed a complete visualization of the flow and mechanics of the game. Later, the construction of the game based on rapid prototype promoted the initial understanding about mechanics and interaction proposed before the development of the complete prototype.

In some cases, the game design thinking results motivated groups to abandon the idea of digital gaming and invest in a board game, given that the board proposal exceeded the digital proposal in terms of gameplay.

Conclusions

This article discusses the main differences between the terms game thinking (gamification) and game design thinking. While for gamification there are a significant number of proposed and proven methodologies, for game design there are few methodologies that really point to design and development stages in an agile and lean way, stimulating inspiration, creativity, innovation, and identification of trends.

Then, a methodology based on design thinking for the game design is presented and discussed in practice, with the report and analysis of case studies results. The results obtained from case studies show the generation of more interesting games when compared to games developed without the use of a methodology that stimulates creativity and innovation such as design thinking methodology.

This study intends to contribute to the area of digital game design and development, either professionally or in activities that involve the learning process.

Synonyms

Game platforms; Game venues

Definitions

Game venue = a physical place where one or more persons can play a video game.

Game platform = a device suitable for playing video games, e.g., a console, a smartphone, or a PC.

What venues do we think of when we think about playing games? The dining room table with a board game, the computer desk in our office, or the living room in front of the TV? The location of the "venue" of a game can be a direct result of how successful the game can become. If we were to design a game, the decision of what platform – console, PC, tabletop, mobile, or tablet – is an important decision to make. For centuries, humankind has revolved around many different aspects when it comes to the social aspects of entertainment.

Studying history we can see how our choices for entertainment and comfort have changed. Just look at the evolution of the TV going from something that we see in stores and restaurants for public entertainment to be a staple inside of the poorest of homes in America. The same can be said about games and the platforms they are running on. In the 1980s, a game console was rarely found in a household, but today, more than 89 million American households own at least one type of game console or a PC. Over 40% of them have multiple types of gaming consoles or platforms (Statista 2018).

The type of games can affect the kind of venues. For a game that tells a grand story with videos and cinematic scenes, a console connected to a big screen in the living room is a good choice. A game that brings people together to spend quality time playing would call for a tabletop game, such as cards or board games. For a massively multiplayer game connecting hundreds of people around the world, a PC would be the best platform.

The main issue with consoles is that it can be limiting and expansive at the same time. Currently, there are three companies who are at constant battle with one another to dominate the console war: Microsoft with their Xbox One X the console which has the fastest graphics and processing speed, Sony with the PlayStation 4 Pro that is a serious contender to Microsoft with their console exclusive games, and Nintendo Switch which has the ability to seamlessly swap from console on the big screen to mobile handheld console in an instant without compromising the current gaming activity.

It is ideal for a game to run on all platforms. However, if, say Sony PlayStation decides to make a game its console exclusive, it would take away

the three-company bliss and cut it down to one, literally reducing the game market size by 66%.

Another consideration is input devices for game platforms. Consoles offer a more limited control through a controller whereas a PC keyboard allows a wider range of controls. The Xbox and the PlayStation controllers only has 12 individual buttons with 2 joysticks, which provide a range of combinations but are less than an average PC with a keyboard of 62 buttons plus a mouse (Rigg 2018). Depending on basic versus gaming equipment, the mouse itself may have extra buttons on it, making it the best contender for button combos and linking actions to buttons. The PlayStation Controller does have one advantage against its competitors, a large Touchpad at the top of the controller. It is designed to allow the player to swipe and click on information very much like a laptop touch pad. So far it seems to only be useful for menu navigation, but with the redesign Sony was planning on a future with new innovative games which will include the Touchpad into their game. Nintendo Switch comes with two controllers, Joy-Con L and Joy-Con R, each of which contains an accelerometer and gyroscope for motion control support. All three companies have designed motion control systems before, Microsoft with the Kinect from Xbox 360 and Xbox One, Sony with the Playstation Move for the Playstation 4, and Nintendo who has been doing it the longest with the Wii, Wii-U, and now finally the Switch. The Switch Joy-Con's are possibly the most accurate out of any companies attempt at motion control. The actions with the controller are spot-on: if you overexaggerate your actions, the results appear on screen as overreacted. It is a finely tuned gyroscope inside of the controller. Not to mention that 9/10 games produced for the Nintendo Switch make use of this motion control, unlike many predecessors which only had a few games made to use the motion control.

There are also arguments between gamers about which one offers a better reaction time: the joystick on a controller versus a PC's mouse. Most gamers agree that the PC's mouse outperforms the console's controllers. In addition, most computers that are built for gaming have a high-quality graphics card and processing power to be able to play games with better graphics quality and reaction time. Nevertheless, Microsoft is closing the gap on PCs by adding keyboard and mouse support on Xbox One in 2018.

While mobile and tablet game platforms are less powerful than consoles and PCs, they have a built-in touchscreen and other features that make them unique. The large amount of people that own a smartphone means that mobile games have a large potential reach. The ability to play games anywhere enables the creation of games that integrate GPS technology. Another application that can be used by game developers is the multiple cameras smartphones possess to run augmented reality, where graphics generated by software is overlaid from pictures from the camera. Games such as *Pokémon Go* has used all of these technologies to allow players to travel to a place in real life and then catch a Pokémon using the touchscreen and augmented reality. For games that would require a proper controller, games can utilize the smartphone's bluetooth technology to allow a user to buy a third-party controller, pair it with the smartphone, and then affix the phone to the top or middle of the controller. Likewise, iOS and Android operating systems allow their users to project their screen onto another device for a better viewing experience.

Game with a Purpose

▶ Hypermedia Narrative as a Tool for Serious Games

Game Writer's Dilemma: Context vs. Story

Ross Berger
Vistance Consulting, Los Angeles, CA, USA

Synonyms

Context; Game writing; Narrative; Narrative design; Storytelling

Definitions

Narrative is a fictional, cohesive universe made up a mythology of characters and settings bolstered by a story (but often a series of stories), theme, and tone. Story depicts a character's journey that, through a series of escalating challenges and accomplishments, results in that character's self-discovery. It is part of a narrative, but, by itself, is not. Context is descriptive, light information that provides a player with justification as to why he/she is about to take on a certain task or pursue a certain goal. It is also filler or casual stimuli, like ambient dialogue, that provide authenticity to a world.

Introduction

There is an industry-wide confusion over the role of narrative in games. Often times, it is confused with context. This entry will define "narrative," "story," and "context" and provide how their applications in the game experience are distinct from one another.

Overview

A writer does not have an enviable role in video games. Sure, game writing beats writing copy for a hardware catalogue. And it is more fun than writing dry text for, say, an academic publication. (Irony acknowledged.) But in the world of video games, writing is often a misunderstood craft and, as such, is often shunted to the side until the very last minute of a game's development.

There are many reasons for this, including (1) people think, because they have the ability to write sentences, that they have the ability to write a narrative; (2) writing does not involve lines of code, thus words are easier to adjust at the last minute to fit features that are perceived to be cool at the time; and (3) gameplay is king and thus story must be subservient to it.

The last point is unassailable. Games are a gameplay-driven medium. If one wants to work in this field as a writer, the first thing he/she must understand is that narrative will need to serve gameplay, not vice versa.

But the other two points are unnecessary yet frequent obstacles that often hinder a writer. Fake understanding of the craft is common and dismisses its burden. A nonwriter's attitude is simply, "I write emails and texts all the time. It's so easy. Anyone can write." Obviously, this facile comment ignores thousands of years of story innovation including compelling characters, plot, structure, and theme. More importantly: crafting words to communicate these requirements of storytelling is not the same as crafting an email. (If so, why not then abnegate the works of Homer and Shakespeare?) But what is dangerous about this attitude is that it lowers quality expectations, encourages amateurs to assume the role of writer when companies are crunched for budget, and does not allow for producers to allocate enough time or personnel for story development.

Writing story is also viewed as a lesser craft than writing lines of code. Accordingly, writers are often pushed to make dangerous compromises on story in order to avoid upending a feature that is hard-coded into the game. It is foolish to say that storytelling is harder than programming. Because it is not. But it is also foolish to say that

storytelling is easily flexible, so moldable to whim. Because it is not. Yet, it is often "strong-armed" by whim to change ad infinitum. Such arbitrary demands are myopic and cavalier, and often lead to the compromise of quality. Story beats will be abbreviated and then combined into a later one, at which time a player will be deluged with too much information. Even worse, casually thought-out rescoping can lead to serious coherence issues.

All of these pitfalls are a result of one common problem: a profound misunderstanding of what narrative is.

This entry will focus on a particular type of misunderstanding (yes, there are many) that does not necessarily over-tax the writer, but nor does it empower him/her to maximize the craft to its fullest capacity. It is the misunderstanding of the term "context." So prevalent is its confusion with narrative that it is the intention of this entry to correct the record once and for all.

What Is Narrative and How Does It Get Misused

In the recent history of game development, narrative has become a "nice-to-have" feature in an industry where gameplay reigns supreme. Of course, there are a multitude of games that are narrative-centric or, at least, that push story as a major feature. (Telltale Games, for instance.)

But narrative still remains, for a significant majority of games, an after-thought to game design due to popular expectations from players. Disruption of the gameplay experience is a high crime, and narrative is often seen that way. Even if the vehicles that deliver narrative are interactive (like cinematics) and offer direct incentives that enhance gameplay (boosts, for example), players often do not look forward to these mini departures. Writers do not welcome this approach either. Narrative gets diluted when it offers incentives to a player just to validate its existence.

For the most part, games are not a narrative-driven medium.

Nonetheless, this does not stop game studios from wanting to include narrative in their games. As they should. But "narrative" is not universally understood. Each game studio, in fact, might have their own definition. To be clear:

Narrative is not text on screen.
Narrative is not writing 27 different ways of saying, "Take cover!"
Narrative is not mission descriptions.
Narrative is not tutorials.

What narrative is, instead, is a fictional universe made up a mythology of characters and settings bolstered by a story (but often a series of stories), theme, and tone.

It does not stop there. Narrative is also responsible for the granular details that buttress these pillars and provide necessary information, authenticity, and orientation for a player's journey.

It is the overemphasis on the granular details, however, which the majority of game companies incorrectly define narrative to be: the minutiae.

So yes, narrative does involve: text on screen; 27 different ways of saying, "Take cover"; mission descriptions; and tutorials. But without a central, cohesive fictional universe, these discrete parts do not add up to narrative.

Individually, they are, instead, context.

What Is Context?

Context is descriptive information that provides a player with justification as to why he/she is about to take on a certain task or pursue a certain goal. It is also filler or casual stimuli, like ambient dialogue, that provide authenticity to a world. (Think of combat chatter in *Call of Duty*.) Context is light information and does not provide enough connective tissue from one moment to the next to be defined as narrative.

Context is necessary in the sense that, without it, players will not understand why they are about to embark upon a certain part of a journey or what the immediate goal will be.

Context also has an important role in reinforcing the fictional universe, be it through communicating the personalities of characters of the game, backstory of the world, or game rules. Tone is also a critical driver of context and vice

versa. For instance, Rolf and Jenny land their ship on a desolate planet, hoping to find a lost ship of fellow explorers. Rolf and Jenny are a married couple and are ambitious scientists with a penchant for puns. When they come across a volcano on the verge of eruption, on-screen text tells them they must cross the volcano to reach the other side of the mountain, where a light beacon assures that they will reunite with one of the lost crew members. Here we have an excellent opportunity to infuse the on-screen text with some of Jenny and Rolf's humor. "They've studied the topology of this planet before. Therefore, the volcano's volatility is no surprise. The only test here is their *lava* for one another."

This type of context informs a player of the following (1): Rolf and Jenny have an extensive knowledge of the planet; (2) Rolf and Jenny knew of the planet's volcanic activity prior to landing; and (3) Rolf and Jenny have a terrible sense of humor.

As long as it reinforces what this world is about and remains consistent, tone can go a long way in adding more flavor to context and, in turn, reinforcing the narrative even if through secondary impact.

What Is Story and How Does It Differ from Narrative?

Story depicts a character's journey that, through a series of escalating challenges and accomplishments, results in that character's self-discovery. Upon that self-discovery (also known as anagnorisis from Aristotle's *Poetics*), a character will face a big decision: Will they change for the better? Will they continue on their path but with larger challenges ahead? Will they do something selfless for the betterment of those around them?

Story is a progression of a hero. Everything he or she encounters along the way should enhance the stakes of that progression and provide more insight into the hero's psyche and past.

Story is a critical part (often times, the majority) of a game's narrative. But story, by itself, is not narrative. Narrative is the bible that is comprised of a series of related stories, characters, and environments. Narrative is the fictional universe, the elements inside, and the connective tissue that binds those elements together. Where story needs a protagonist, narrative needs a world or universe of which that protagonist is a part. Where story moves forward through plot, narrative moves forward through mythology and world building. Where story is the single journey of a single hero, narrative is potentially an endless series of journeys and incorporates many heroes.

Why Is Not Context Story?

The light information that context provides is critical to orienting a player on their path forward. But it is not an ideal vehicle for story as it can hamper a player's momentum. Stopping to read long tomes of story will engender resentment from most players. And bite-sized, frequent appearances of on-screen text are met with equal disapproval. These instances happen more frequently than one can imagine.

Context should never be expected to do the heavy lifting for story. A few reasons why (1) a mission could be added after the development of the story has been "baked" and is therefore inelegantly shoe-horned into the core progression; (2) one-off activities (e.g., sports drills, tutorials, missions, live raids, etc.) may not be thematically or structurally related, and therefore imposing a faint connection that ties them together will, most likely, dilute or neuter story; (3) the game is comprised of an endless stream of missions or grinding activities in which ongoing story would fail in quality or logic to serve as an effective complement.

However, context would still be appropriate to give a player an understanding of basic stakes and consistency to the world that was already set up in the narrative (assuming a narrative was established in the first place).

But due to its nature, context does not move the story forward. It provides ancillary, and sometimes inconsequential, information that keeps a player aware of stakes. But there is nothing in that information that contributes anything emotional or meaningful to the hero's psychological journey, the main force behind story.

Context is narrative in its lowest, most unambitious form. It is one step above stimulus.

Cause for Confusion

The most common use of context in games is through on-screen text and informational voice-over, which are very attractive for game developers as they provide low cost solutions for tutorialization and player orientation.

But to label words on screen or informational voice-over, without having any other elements of narrative, *as narrative* is to diminish the craft of writing. This oversight or lack of understanding by video game professionals is neither malicious nor negligent. One can attribute the prevalence of the misuse of these terms to the rise of social media.

Due to the increased volume and accessibility of content creation tools on mobile, terms such as "story" and "narrative" have become less clear now that social media companies have co-opted those terms to mislabel new digital products. *Snapchat My Story,* for instance, is often a collection of disconnected videos that do not build to a cohesive message. *Instagram Story* is no different in result (other than it features photos only). It is the culture – not the game developer – that has obfuscated the meaning of story.

Conclusion

Narrative, story, and context are often used synonymously in game development; however, as described above, they are not the same. As media changes, so does the craft of writing. Keeping up with how stories are told year after year remains a challenge for writers. So, too, does the ability to communicate the distinctions between narrative, story, and context.

Video game story professionals need to tackle that task effectively. Doing so will result in realistic expectations from engineers, designers, and producers, and will empower writers to advocate for narrative in ways that it deserves.

It is the hope of this author that nonwriting professionals in game development will soon understand that pushing narrative to its artistic maximum (including its original intention) will result in higher quality games, no matter the genre.

Game-Based Interventions in Public Health: Exploiting the Engaging Factor of Gameplay

Synonyms

Game-based approach; Games for health; Gamification; Health games; Serious games

Definition

Game-based intervention in public health: *exploiting the engaging factor of gameplay* is the application of game science, techniques, and technologies for supporting public health

interventions, specifically focusing on serious games and gamification approaches. Serious games refer to digital game technologies that serve a purpose other than pure entertainment, and gamification is a technique that exploits game concepts and mechanics in non-game contexts in order to motivate engagement and sustain participation in serious activities.

Introduction

The increase of health impediments due to unhealthy lifestyle has put a lot of pressure on public health spending. Even though public health programs are important in raising awareness toward lowering the prevalence of physical and psychological health complications, the general public should be made accountable for their own health and well-being. The approaches by which awareness is raised, attitudes and behaviors are transformed, and positive habits are nurtured should be improved to be more effective, which could potentially ease pressure on public health services in the long run.

The level of receptiveness to public health awareness programs is highly subjective to whether positive engagement, persistent involvement, and discourse can be fostered. There is a growing interest in improving and sustaining engagement with such programs across the healthcare sector using technologies, such as digital games. Games such as America's Army, for instance, are able to reach a large number of players and engage them for long periods of time, which has encouraged gaming to be used to achieve serious outcomes, such as cognitive gain, awareness raising, and change of attitude and behavior.

Games as positive technology capitalize on its engaging and fun characteristics toward fostering positive emotions, nurturing positive habits, encouraging positive attitude and behavior, and promoting optimal human functioning. Game approaches can be used as an enabling tool and/or concept to promote qualities that could enable individuals and communities to strive for and build the best in life. McGonigal (2011) and others have continued this approach, leading games for change projects that raise awareness and support good causes or try to change behavior for social purposes. Self-regulation and health coaching, for instance, have a big potential to empower individuals, and combined with mobile and social platforms, game-based approaches could facilitate community building and peer support system around healthy lifestyles in a more pervasive and active way.

The need for efficient and effective education of healthcare professionals has also seen game-based approaches employed in a diverse range of forms to address training needs, while in a clinical setting, games have been used to improve therapeutic outcomes for patients. Fundamental to the success of game-based intervention across these areas is the ability of designers to realize the power of interactive and immersive environments to engage and immerse the users while conveying learning outcomes in a demonstrably effective fashion. Research, therefore, must play a key role in identifying the strengths, weaknesses, and best practices in the use of game technologies and techniques in the healthcare sector, providing decision-makers with the evidence they need to consider their value as a solution.

With these perspectives, this chapter provides an overview of the implications of using game concepts and technologies for supporting health interventions and discusses key development trends and challenges. The next two sections, respectively, introduce serious games and gamification initiatives, discuss their contributions to and potential in health interventions, and conclude with lesson learned and trends in the domain. The conclusion section summarizes and highlights key takeaways from this chapter.

Serious Games and Health

By definition, serious games refer to applications developed using computer game technologies that serve purposes other than pure entertainment. The term has been used to describe a variety of game types, particularly those associated with

Game-Based Interventions in Public Health: Exploiting the Engaging Factor of Gameplay,
Fig. 1 Screenshot from "Privates" game (www.sizefivegames.com)

e-learning, military simulation, and medical training. Serious games capitalize on their ability to reach target audiences who are already engaging with interactive, rich graphic games recreationally, allowing them to convey instructional outcomes to audiences resistant to more formal methods.

The application of games within the health sector ranges from tackling sexual and mental health to promoting healthy living and raising awareness on pharmaceutical processes. The Privates game (Fig. 1), for instance, has been commissioned by UK's Channel 4 TV Company to engage and educate young people on sexual health issues. Other entities such as the Parliamentary Education Group, DEFRA, and the US government (who held a competition around games for health) are also increasingly commissioning games for learning purposes (Ulicsac 2010). Physical and mental rehabilitation has been promoted via the PlayMancer game, which was awarded the Best European Health Serious Game in 2011 at the Fun & Serious Games Festival in Spain. Most recently, the EU-funded PEGASO project exploits game technologies to support an ecosystem of beneficiaries in addressing challenges related to obesity, a worldwide public health problem (Panese et al. 2014). Inspired by the success of FarmVille, a pharmaceutical brand Boehringer Ingelheim releases their own game – Syrum – aimed at demonstrating the brand's continuous commitment in research and innovation and to educate the public on their product development process.

Recognizing the increasing popularity of digital games in health applications, there is a need for empirical studies to be carried out that can serve as benchmarks for establishing scientific validity for the efficacy of such an approach. This is a critical trajectory for the application of games within the healthcare contexts as to encourage uptake within formal deployment; existing initiatives should move "away from the evangelistic early stage work to the practicalities of implementing and testing game technologies in real contexts of use" (Arnab et al. 2012). For example, several important studies have been undertaken that have shown the efficacy of game-based approaches over traditional approaches (e.g., Hainey et al. 2011; Kato et al. 2008; Knight et al. 2010; Marchiori et al 2012; Brown et al. 2012; Arnab et al. 2013). The first controlled trials for game-based intervention (Kato et al. 2008) showed how game-based approaches in the Re-Mission game (Fig. 2) fostered medication adherence in children with cancer.

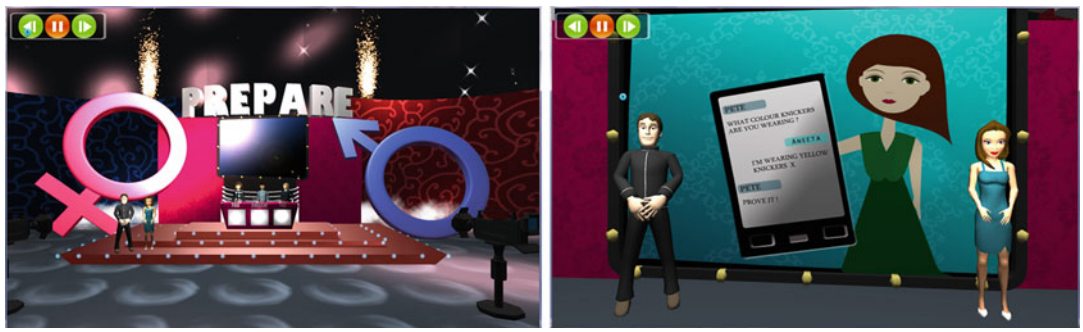
Other examples include a game-based intervention to support the delivery of relationships and sex education (RSE) program (Fig. 3), a game called PR:EPARe (Positive Relationships: Eliminating Coercion and Pressure in Adolescent Relationships) developed by the Serious Games Institute and the Studies in Adolescent Sexual Health (SASH) research group at Coventry University, UK (Brown et al. 2012; Arnab et al. 2013). A cluster-randomized controlled trial in local schools ($n = 505$) demonstrates positive outcomes in favor of the game-based

approach when compared to existing methods based on surveys of self-reported measures of psychosocial preparedness for avoiding coercion or coercive behavior. The *Serious Games for Healthcare* book (Arnab et al. 2012) highlights existing research and development trends, methodologies, and experimental work in the use of game technologies to address health-related topics, which aimed at progressing the understanding of serious games, the methodological rigor, and the implications. This volume explores the issues including ethics, modern game engines, design considerations, and research methodologies underpinning the use, evaluation, and validation of games applications.

For a game to be considered "serious," its efficacy should be proven rather than simply intended, and games should not be afforded exemptions from the rigor applied to assessment of other approaches to education and training across the sector. Only then can relevant decision-makers be provided with the evidence needed to make informed selections of game-based approaches as ideal solutions to specific intervention, learning, or training needs.

The study on the long-term behavioral impact is however longitudinal. Games' ability to reach and engage a large number of players for long periods of time provides an opportunity for vital user data to be recorded, monitored, and analyzed continuously. The challenge is how to best collect, record, and analyze the potential wealth of data and utilize the analysis to provide appropriate feedback and support to the individuals, which could potentially promote self-management and health coaching.

Game-Based Interventions in Public Health: Exploiting the Engaging Factor of Gameplay, Fig. 2 The Re-Mission game (Kato et al. 2008)



Game-Based Interventions in Public Health: Exploiting the Engaging Factor of Gameplay, Fig. 3 Screenshots of the PR:EPARe game (Arnab et al. 2013)

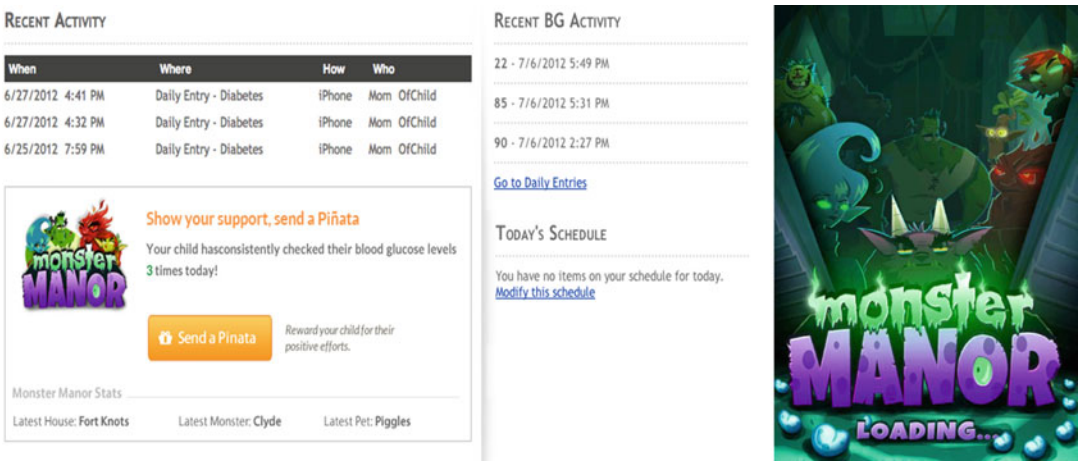
Gamification and Health

The need for a more long-term regulation of healthy behavior signals a move toward greater gamification, commonly defined as the use of game design elements in non-game contexts (Deterding et al. 2011). It will take the essence of what it is that makes games so appealing, decode the mechanics that makes them work, and then apply these mechanics in activities that activate psychological motivators, which in turn drive desired behaviors. A strong body of research work has already been generated and the number of new publications on gamification is growing daily, as underlined in a recent study (Hamari et al. 2014).

The pervasiveness of game (play) mechanics and dynamics employed in day-to-day activities to support serious outcomes is the current trend within the context of gamification. Gartner (2015) expects gamification to reach the "plateau of productivity" within 5–10 years; that is, mainstream adoption begins to take off and more rigid assessment criteria are evident. At this stage, the technology's general market applications and relevance are accepted (Gartner 2015). The biggest players exploiting this trend include the major health insurers such as Aetna, Cigna Health, UnitedHealth, and WellPoint. The main objective is to improve the health and health-related knowledge of their employees, which will subsequently help increase productivity and reduce health insurance premiums.

By tapping into our natural tendency to react positively to entertainment and the competitive nature of most gameplay, actionable steps to overcome personal challenges can be designed. This can potentially help initiate healthier activities in any number of areas: losing weight, sleeping more, making healthier food choices, improving fitness, monitoring health metrics, and medication compliance. Most of the activities will however require individuals to embrace delayed satisfaction, where the reward may be as elusive as the prevention of a chronic condition. With this perspective, gamification allows rewards and incentives to be used to sustain positive engagement. The fundamental fact of motivation is that we cannot be forced to change our behaviors. Behavioral change may be initiated by extrinsic sources of motivation or external factors that influence how we behave (Seifert et al. 2012).

Intrinsic motivation and positive habit may be nurtured through sustained engagement, where personal incentives and rewards for healthy behavior could be discovered. For example, the Monster Manor gamification program (Fig. 4) involves parents and clinicians in the "playful" and "incentivized" ecosystem aiming to motivate children with



Game-Based Interventions in Public Health: Exploiting the Engaging Factor of Gameplay, Fig. 4 A support and rewarding system – a child plays Monster Manor, checks their blood glucose level, and receives a reward for positive efforts to be used within the game (www.ayogo.com)

Game-Based Interventions in Public Health: Exploiting the Engaging Factor of Gameplay, Fig. 5 The Walk commissioned by the UK's Department of Health and National Health Services (NHS), exploiting the success of Zombies Run (www.thewalkgame.com)

type 1 diabetes to check their blood sugar regularly. The testing schedule was paired with a reward schedule in a virtual world of "pet monsters." Parents and clinicians can also intervene in this "Monster Manor" virtual economy to reward children for consistent checking. Other examples include an online and social community facilitated by the HealthSeeker program utilizing on competitions and recognition, where adults issue health challenges to each other through Facebook. Successfully completing shared "missions" will result in points that allow players to progress through the levels of the game. Analysis of the resulting data indicates that these peer-to-peer challenges are substantially more effective at encouraging change than simple software-originated challenges.

The pervasiveness of play spaces has seen gamification exploiting actual gameplay in both the physical and digital spaces. Games such as Zombies Run and The Walk (Fig. 5) exploit location-based mobile gaming to advocate running and walking, respectively. These initiatives intrinsically encourage "players" to run or walk as part of the mechanics for the location-based adventure game instead of explicitly campaigning about the benefits of running or walking as a fitness regime. Pervasive gamification, when coupled with wearable technologies, opens up exciting opportunities for individuals, who are not normally engaging with digital games to participate in positive playful activities anywhere and at anytime. Applications such as FitBit and Nike+ capitalize on mobile and wearable technologies and the common features of gamification (points, badges, and leaderboards).

Taking into account the behavioral challenges restricting the reach and effectiveness of health interventions, gamification could help to revolutionize the existing intervention for the general population into incentivized, future-looking, preventative, and personalized healthcare. Personalization provides individuals with a sense of control over their own healthcare. The benefit of gamification within the health sector is longitudinal and will require rigor in the evaluation of long-term efficacy. With the advancement in data tracking and analytics, qualitative assessment can be paired with data from the gamified activities to better understand the individuals and continuously provide personalized feedback within the engagement loop.

Conclusions

The use of game technologies and techniques in the form of serious games and gamification presents an opportunity for the engaging mechanics and dynamics of gameplay to be exploited in order to promote receptiveness to the serious message of public health campaigns. Longitudinal engagement with gamified platforms allows the facilitation of the recording and reasoning of large-scale health and well-being data. By better understanding knowledge, attitude, and behavior of the "players" and assessing their progress continuously, personalized and actionable feedback can be provided to nurture healthier habits. The academic labeling and debate by semantics and taxonomy quantize the differences between

gamification and serious games. However, the aims of any of these terms are that they are all trying to solve a problem and motivate using game-based thinking and techniques (Kapp 2012).

The generations who grew up playing electronic games increasingly represent and include both professionals and decision-makers in the healthcare sector, which makes increased receptiveness to this form of instruction becoming more apparent. If this receptiveness is coupled with the research required to validate and refine the use of game-based approaches across a wide range of applications, this may lead to exciting opportunities to address challenges existing interventions have so far failed to satisfactorily overcome. As the public health sector increasingly pressed to tackle chronic diseases and behaviors among the general population, the introduction and discussion put forward by this chapter, alongside the past and current projects in the area it highlights, suggest game-based interventions may form a critical part of a long-term strategy to address these challenges.

The diminishing boundaries between physical and digital spaces provide great opportunities for game-based approaches to be applied in everyday contexts. Game mechanics are becoming more pervasive as real and virtual interactions and events are merged within the context of gameplay. The application of gamification and pervasive gaming, such as The Walk and Zombies Run demonstrates the potential for gameplay to be a key catalyst for the nurturing of long-term healthy behavior. As the sophistication of mobile and wearable technologies is advancing, for instance, the potential for a more connected and seamless gameplay experience within a hybrid space will be possible.

The future trend in games and gamification will thus exploit such a hybrid space, which will see the crossings between pervasive gaming and gamification that will inject gameplay into their surroundings and community. The advancement of the Internet of Things (IoTs), mobile technology, and data analytics will allow everyday spaces to be transformed into a personalized playground enriched with contextual resources and activities. Self-reinforcement of personal healthcare will be more enhanced and engaging, relevant, and ubiquitous. Anytime, anywhere healthcare when gamified will introduce playfulness, competition and collaboration-playful healthy "regime," competition to drive self-improvement, and collaboration to foster a community of health-conscious citizens.

Research plays a key role in experimenting and providing evidence in the use of game technologies and concepts in the healthcare sector. The prospect of a gamified and pervasive health and well-being ecosystem can potentially affect the design and deployment of health strategy and policy in the future. Despite significant challenges for researchers in this domain in terms of the lack of standard methodologies or formulaic frameworks that guarantee success and efficacy, there are some empirical studies that can serve as benchmarks for establishing the scientific validity. There is thus a need to tap into best practices of such a multidisciplinary domain and infuse knowledge from relevant disciplines within the application domain toward developing an infused and transdisciplinary methodological framework that may act as a validated guide to inform the development process of a game-based approach.

Games and Active Aging

Inês Amaral[1,2] and Frederico Fonseca[1]
[1]Instituto Superior Miguel Torga, Coimbra, Portugal
[2]University of Minho, Braga, Portugal

Synonyms

Active learning; Active videogames; Cognitive games

Definition

Games are an important toll of active aging as they enable knowledge acquisition processes, attribution of meaning to information, and enhance quality of life and psychological wellbeing to the older people.

Introduction

The aging of the population is one of the main challenges facing contemporary societies. As a result of a shared social construction, there is a discursive "requalification" of aging, associating it with a terminological plurality that deconstructs the prevalence of negative stereotypes that associate old age with dependence, lack of autonomy, disease, institutionalization, and a disregard of their heterogeneity.

Social exclusion of the elderly is a consequence of globalization as well as the condition of second-class citizenship (Amaral and Daniel 2016) for those who do not have access to digital capital. Games can enhance quality of life of the elderly in three perspectives: cognitive, sensorial, and physical (Costa and Veloso 2015).

Active Aging

The requalification of aging has emerged with organizations such as the United Nations and the European Union that, since the 1980s and 1990s, have launched the concept of "Active Aging." New approaches and political solutions have leveraged this notion as a social representation for political and media discourses, seeking to combat the stereotypy that produces negative aging. The term "active aging" is the successor of concepts such as "healthy aging" or "successful aging." In 1997 the World Health Organization, inspired by the United Nations Principles for Older Persons, presented the concept of "active aging" as "the process of optimizing opportunities for health, participation and security in order to enhance quality of life as people age" (2002). Active aging is a concept that promotes the wellbeing of the elderly and includes the dimensions of health, participation, security, employment, independence, autonomy, and integration (Parra 2013).

Quality of life of older people may be affected within three macro-areas such as physical capacity, sensory capacity, and cognitive capacity (Parra 2013). Therefore, there is a need to create "innovative ways to re-invent strategies for sustainable active ageing and healthier lifestyles" (Costa and Veloso 2015).

Games and Active Aging

Games' approaches focused on healthy and positive aspects of individuals are transverse to the theoretical and empirical scientific contributions in this field. The individualization stands in the mainstream of political agendas to value the individual as a builder of his life course. The Declaration of Alma-Ata (1978) appeals to health for all and the need for health promotion models that avoid the traditional top-down logic (WHO 2002). It is the recognition of people's participation in promoting their citizenship as "the right and duty of the people to participate individually and collectively in the planning and delivery of health care" (WHO 2002). Giving digital competence to older people is a way to empower them as this concept may be assumed as a transversal key competence that enables the acquisition of other skills, as the European Commission has broadly defined it. Games can be a way to promote a critical and creative use of the ICT to achieve goals that may be related to health, work, leisure, learning, inclusion, and participation in public life.

The games may enable self-learning by providing meaningful active learning experiences (Costa and Veloso 2015), as well as embody mental and emotional representations. Digital games can improve the quality of life of the elderly in particular with regard to reaction time, visual perception, and eye-hand coordination (Green and Bavelier 2007; Bialystok 2006). Previous research demonstrated that these benefits are related to increased dopamine levels in the brain,

which decline with age, and are elicited by digital games (Green and Bavelier 2007; Parra 2013).

Exergames can be used to motivate older adults to engage in healthy activities in a positive way. These games are designed in order to prevent physical decline and preserve and even physical abilities such as muscle strength and balance (Parra 2013). Serious games can stimulate cognitive functioning skills that positively affecting psychological wellbeing (Parra 2013). Monitoring applications can also be used to analyze user's behaviors such as reaction time, short-term memory, and discernment. These applications inform the doctor of the evolution of the elderly's performance over time, allowing planning or adjusting therapies that may improve the psychological wellbeing.

Conclusion and Discussion

Games have the capacity to improve quality of life of elders and contribute to their active aging. The dimensions of health, participation, security, employment, independence, autonomy, and integration are promoted by the use of games, fostering lifelong learning through digital inclusion. Stimulation of cognitive, sensory, and physical abilities can be achieved with tangible and nontangible interfaces. The learning curve is also an important factor that supports the evaluation of the elderly. Gaming can be an integration tool and not necessarily a therapy, as it can also be integrated in the context of health.

Games and the Magic Circle

Douglas Brown
Games Academy, Falmouth University, Cornwall, UK

Synonyms

Playground; Play space

Definition

In the context of games, the magic circle is the area within which the rules of the game apply, a special space, ideally but not necessarily demarcated by the rules within which play occurs. It need not be a physical space, but can instead be virtual or a frame of mind.

Introduction

The magic circle is a concept still widely used and referenced by games studies scholars and games designers and is both helpful shorthand and a problematic theory. This entry will look over the history of the concept and explore the issues and controversies it raised, with a particular eye toward games studies' frequent criticism of the concept. Despite its contested and controversial nature, the magic circle borders on other central concepts of games studies and games design including play, immersion, and suspension of disbelief, and these linkages are also something this entry will explore.

History

The magic circle was a term first used as part of Johan Huizinga's seminal study of play, *Homo Ludens*. While it is only mentioned only a few times in the English translation of this text, it is regarded as a primary metaphor for how play occurs, as explained when the term is first used:

> All play moves and has its being within a playground marked off beforehand either materially or ideally, deliberately or as a matter of course. Just as there is no formal difference between play and ritual, so the "consecrated spot" cannot be formally distinguished from the play-ground. The arena, the card-table, the magic circle, the temple, the stage, the screen, the tennis court, the court of justice, etc., are all in form and function play-grounds, i.e. forbidden spots, isolated, hedged round, hallowed, within which special rules obtain. All are temporary worlds within the ordinary world, dedicated to the performance of an act apart. (Huizinga 1955: 10)

It is important to note here that Huizinga sees play as behavior distinct from the everyday norms of society, but does not ascribe triviality to play – hence why lawcourts are as valid play spaces as card tables or magic circles.

Huizinga's seeking out of play spaces was also grounded in the discourse of cultural studies, far from actual game design practice, as Calleja's discussion of the concept makes clear (Calleja 2012). This is why the magic circle concept most usually used in games studies in particular is just as much rooted in Katie Salen and Eric Zimmerman's definition and retooling of Huizinga's concept in their 2004 book *Rules of Play*, one of the first major games studies textbooks and a substantive games design resource. To Salen and Zimmerman, the magic circle is a potent metaphor of real use for game designers. They first define the concept in a way similar to Huizinga but assert that the physical element of the spatial magic circle is not mandatory:

> In a very basic sense, the magic circle of a game is where the game takes place. To play a game means entering into a magic circle, or perhaps creating one as a game begins. (Salen and Zimmerman 2004: 95)

Later in the book, they also discuss the magic circle as a form of boundary but also a kind of special space or context for the game created by the player:

> Beginning a game means entering into the magic circle. Players cross over this boundary to adopt the artificial behaviors and rituals of a game. During the game, the magic circle persists until the game concludes. Then the magic circle dissolves and players return to the ordinary world. (ibid: 333)

Salen and Zimmerman's magic circle reinforces the view that games create their own contexts, so that the differences between a person's playing with a physical game piece while not playing a game with it and doing so during a game session is brought into stark relief, since there is now a magic circle operative.

State of the Concept

The magic circle concept sits in a useful place for introducing games as objects of study and is an extremely accessible gateway to more complex concepts such as liminality, presence, the suspension of disbelief, and the lusory attitude (Suits 1978). It also functions as a useful metaphor for game designers to discuss games and their

potential while enshrining a degree of ambiguity about the space where rules, play, and gamers collide.

Ever since Salen and Zimmerman's definition of the magic circle, the term has not been off the radar of games studies academics, who frequently question, dismiss, or attempt to redefine it. As such, using it in an unqualified fashion is not advisable to games studies students new to the concept.

Issues and Controversies

Attacking and interrogating the magic circle concept was so prevalent for a time in games studies that there was even a conference in 2005 convened around "breaking the magic circle." Zimmerman quips when looking back over the history of games studies since *Rules of Play* was published that:

> It seems to have become a rite of passage for game studies scholars: somewhere between a Bachelor's Degree and a Master's thesis, everyone has to write the paper where the magic circle finally gets what it deserves. (Zimmerman 2012).

Scholars generally have two principal problems with the magic circle concept – either that the circle's boundaries are permeable and things can travel through them both ways or that the magic circle concept is reductive, outmoded, or unhelpful and would be better left behind. The idea of a privileged space where gameplay occurs also makes the figure of the critic awkward. Can a critic stand outside the magic circle and meaningfully comment on what goes on on the other side of the boundary?

For some critics coming from particular areas of games studies such as gamification or educational games, the very concept of a magic circle is unacceptable, as the texts with which they are concerned constantly strive to handle the transition between in-game and out-of-game information, be it advertising material or learning curricula.

The magic circle's ambiguity and its imperfection as a game system model drives other critics who would see it removed or replaced. The awkwardly inexplicable "magic" of the circle (and it is no accident that Huizinga chose the magic circle, rather than the other playgrounds he lists, as emblematic, since "magic" implies a tangible link to ritual spaces) which centers around the self-reflexivity of play is where Klabbers (2009) situates arguments for renovation of the concept best articulated and discussed in a critique by Myers (2012).

Other criticisms run the gamut from the explicit link to ritual which persists in the "magic" element of the phrase, its growing irrelevance as an increasingly networked society spends time often in parallel virtual and non-virtual spaces, or its implied dichotomy between work and play through to the value of the pragmatic approach to the concept taken by Salen and Zimmerman in their redefinition. The existence of magic circles around digital games in particular, where possible play actions are often unalterably authored into the system, is often challenged (Calleja 2012).

While there are many perceived and well-articulated problems with the concept, a majority of the papers written on it fall into the trap of attempting to replace the magic circle with a system of their own design, while more considered scholarship (Consalvo 2009) suggests the adoption of sociologist Erving Goffman's broader approach of frame analysis in its place. Many other critics try, if not to replace the concept wholesale, then to repair it in order to make up for perceived deficiencies. Castronova takes up the concept's permeability as a virtue, seeing markets, politics, and law pass in and out through what he redefines as a "membrane" thrown around the text by the magic circle. He still eventually declares that, at least in the case of the MMO-RPGs which he is discussing:

> What we have is an almost-magic circle, which seems to have the objective of retaining all that is good about the fantasy atmosphere of the synthetic world, while giving users the maximum amount of freedom to manipulate their involvement with them. (Castronova 2005: 159–160)

In the retrospective cited above, Zimmerman himself takes responsibility from Huizinga for the controversial redefinition of the magic circle, but defends the concept as a worthwhile game design metaphor, rejecting the way it has been read by

many as a hard boundary hiving games off from the outside world. He does this while pointing out the exaggerated way many of the critics of the magic circle style their offerings to attack straw man arguments instead of actually focusing on the perceived deficiencies of the magic circle. While it is not an ideal metaphor, he contends, the kind of reductive formalism which it has been linked to does not really exist in scholarship, the concept is generally accepted as what it is – an imperfect metaphor.

Other games studies academics are more embracing of the core ideas represented by the magic circle and suggest not their own interpretations of the concept nor its replacement, but rather actively seek to repair it. In his response to various magic circle controversies, Jesper Juul defends the idea of the magic circle as a boundary, but sees it as potentially an awkward metaphor. His suggested replacement is the idea of a puzzle piece:

> Perhaps the problem with the magic circle *as a metaphor* is that it suggests a uniform interface between the game and that which is around the game. We could alternatively describe a game as a puzzle piece. This makes it easier to talk about some of details surrounding games: a puzzle piece has different interfaces on its sides. Seen as a puzzle piece, a game may or may not fit in a given context. We can then analyze *how* a game fits into a context, no longer arguing *whether* games are separate or not. (Juul 2009: 8)

Like Zimmerman, Juul also sees the controversies around the concept as overblown and points toward academics' tendency to seek out and challenge binary dichotomies, often for short-term political ends as partly culpable for the sheer amount of criticism and debate the concept has received. His is possibly the most accepted rehabilitation of the magic circle metaphor into a tool useful for modern games studies, even if the original concept is of use to games designers and those outside of the scholarly arena.

Conclusion

While the concept of the magic circle is undoubtedly problematic, it also feels core in many ways to games and game studies, and the field would certainly be weaker without both it and the debate which its prominence has engendered. The idea of magic circles, be they bounded off playgrounds or chalk lines on the ground generating a special place in time and space where gameplay happens, is enticing, but also extremely broad and open to interpretation. Drawing attention to the border regions of games can be worthwhile, as shown in the context of social, material, and cultural elements by Stenros (2014) in a fruitful paper also trying to rehabilitate both Huizinga and Salen and Zimmerman's magic circles and show that the concept(s), ambiguities, and all hold a place in the modern games studies lexicon.

Games in Science

Christian Stein and Thomas Lilge
gamelab.berlin, Humboldt University Berlin, Berlin, Germany

Synonyms

Citizen science; Crowdsourcing, scientific games; Educational games; Games with a purpose

Definition

Games in Science are used for scientific purposes, like crowdsourcing scientific problems, collecting data from gamers, educating the gamers, or gamifying science itself.

Introduction

Games are not only used for entertainment but also for several serious purposes. Academia has used games for research and knowledge generation as well as for teaching and knowledge transfer. It has been proven that some complicated scientific problems can be solved much better by human players than algorithms. If it is possible to transfer a problem into an entertaining game structure, it could possibly be crowdsourced to a worldwide gaming community. Motivated by game mechanics and the higher purpose of helping science, many players have invested a tremendous amount of time in these games.

One of the most popular examples of this strategy is Foldit, an experimental computer game in which the player folds protein structures as perfectly as possible. The game has been developed in 2008 at the University of Washington. The best scores are analyzed by experts. In 2011, Foldit players helped to decipher the structure of the Mason-Pfizer monkey virus in only 10 days. The problem had remained unsolved for 15 years before (http://fold.it/; Cooper et al. 2010). Science Games like these are not only simulations but actively include game elements like points, badges, and leaderboards to engage players. Science games like these are useful in every field in which humans outperform algorithms (Hand 2010).

Citizen science games are created equally to allow gamers to actively participate in research as to raise interest and awareness about science-related topics. An example of a citizen science project in which citizens are helping researchers is Galaxy Zoo, created by a university collaboration between Oxford, Portsmouth, and Johns Hopkins. Over 150,000 players have helped to classify unknown galaxies within only a year. Researchers could not have done this work in years that players achieved in under a month. By now, there are many projects within Galaxy Zoo following different astronomical cartography goals (https://www.galaxyzoo.org/).

Another area of Games in Science is covering games that are built to generate data about the players while being played (Raykar et al. 2010). A well-known example is NeuroRacer, which was developed in 2013 by the University of California. The player has to multitask, as he is steering a car while he has to react correctly to some color codes shown. The graphics of the game were very simplistic, as the game was relying fully on the mechanics. The game was used to measure the effect of

game-based multitasking training for elderly test subjects with an EEG (https://neuroscape.ucsf.edu/technology/#neuroracer). Although the results of the study were questioned later, it became a well-known example of how to create experiments with video games and measure the training effect of gaming to the brain (Abbott 2013; Anguera et al. 2013).

A growing field that is called Science Games is covering games for teaching, experimenting, and education. A well-known example is A Slower Speed of Light, developed in 2012 at the MIT Game Lab. It aims to teach the player about the relativity of space time, as the game setting alters the speed of light. The player is supposed to collect a number of objects in a three-dimensional setting, and with every object the speed of light is lowered. This way a very complex topic of physics is made tangible and experienceable for a broader audience (Kortemeyer et al. 2013).

But also existing games that were built mostly for entertainment are used for scientific purposes. In the very popular game Minecraft, players can create their own architectures, machines, and structures by crafting and building blocks (https://education.minecraft.net/). This game has been used as a basis for project Malmo, which is an artificial intelligence experimentation platform. With this open-source platform, researchers can set experimental AIs into the world and observe how they learn to collaborate and interact with each other or human players. This way solutions can be tested and compared and allow for the integration of a huge base of human players. Minecraft has also been used for teaching in an engaging way. In a special educational edition, topics like math, physics, history, humanities, or computer science are integrated in a playable way (https://www.microsoft.com/en-us/research/project/project-malmo).

Gamification

Antti Knutas
Lappeenranta University of Technology, Lappeenranta, Finland

Synonyms

Applied gaming; Funware; Ludification; Playful design

Definition

Gamification is the intentional application of game elements to nongame contexts, with the intention of creating playful experiences or gameful interaction. It is often used to motivate and increase user activity or user retention.

Introduction

A synthesis by Seaborn and Fels (2015, p. 17) that considers seminal works on gamification (Deterding et al. 2011; Huotari and Hamari 2012) defines gamification as the "intentional use of game elements for a gameful experience of non-game tasks and contexts." In this gamification is different from serious games, which involve the use of full games in serious, nongame contexts.

Gamification has been used to increase engagement in education (Auvinen et al. 2015), compliance and satisfaction in healthcare (Stinson et al. 2013), user activity in sharing economy (Hamari 2017), and quality and performance in crowdsourcing (Liu et al. 2011; Massung et al. 2013). Currently most common fields for applying gamification are e-learning, sustainability, and motivational software (Kasurinen and Knutas 2018). Successfully applied example from the mobile application industry is the "Run, Zombies!" exercise game, which uses the storyline of running away from monsters to help the player regulate their pacing when running. Additionally, the player can collect virtual supplies for the game's home base while jogging. Another example from city design is musical stairs, which combine fun and curiousness to encourage people to use the stairs instead of the escalator.

The use of gamification often involves the use of common game design elements, such as stories, rules, goals, feedback, and tiers. However, in successful gamified design, user experience is more important rather than the visual manifestation of certain elements (Deterding 2014). Just like in game design, in gamified design the system has to be considered in its entirety from the perspective of the user, instead of adding a set of elements, such as points or badges.

Gamified design and gamification has also faced critique, especially in cases where a stock approach of gamification has been added on top of an existing system in so-called "pointsification" (Kapp 2012). However, gamification has potential for successful results if the system is selectively designed, allowing for personalization and customization, in order to accommodate individual users, and if the design is informed by end users' intrinsic motivators (Seaborn and Fels 2015).

Theoretical Foundations

The dominant theoretical framework for gamification is currently Self-Determination Theory (SDT), as developed by Deci and Ryan (2000), and the most common design theory is user-centered design (Seaborn and Fels 2015). In user-centered gamification design, the main priority is providing an experience for the user and designing with the user's needs and desires in mind (Nicholson 2012). Theoretical frameworks for gamification that follow self-determination theory (e.g., Aparicio et al. 2012) posit that effective gamification is about using game elements to support users' innate need to seek out novelty and challenges, or intrinsic motivation (Ryan and Deci 2000). These three principles according to SDT are:

- Relatedness: the universal need to interact and be connected with others.
- Competence: the universal need to be effective and master a problem in a given environment.
- Autonomy: the universal need to control one's own life.

Design Frameworks for Gamification

There have been several gamification frameworks published, of which Deterding's Method for Gameful Design (Deterding 2015) is one of the most recent and most comprehensive. It is based on the Player Experience of Need Satisfaction (PENS) model, which is based on self-determination theory. First the method uses PENS to analyze what players find motivating and enjoyable qualities in gameplay. Then, it provides a framework to examine gameful design through elements of interconnected challenges, in which the player is taking actions in pursuit of goals, within the system's rules. It posits that gameful design should use the skill-based challenges that already are inherent in the activity that the gameful design supports, with a data-driven design process guided by iterative prototyping.

Two other often used gamification design frameworks are for education (Kapp 2012) and business (Werbach and Hunter 2012). Kapp's approach for education is partly inspired by serious games (Deterding 2015), and Werbach and Hunter's pattern-based approach is intended for motivating users of business platforms.

Conclusion

Gamification is a powerful technique for engaging users through gameful and playful design, supported by a thriving multidisciplinary field and an increasing number of design theories and frameworks (Nacke and Deterding 2017; Seaborn and Fels 2015). However, it is not an easy approach or a one size fits all approach. Care should be taken when choosing design elements and designing for user experience.

Synonyms

Game-Based Learning (GBL); Interactive learning events; Mixed reality serious games; Simulations

Definition

A *video game* is a mental contest, played with a computer according to certain rules for amusement, recreation, or winning a stake (Zyda 2005).

A *digital game* refers to a multitude of types and genres of games, played on different platforms using digital technologies such as computers, consoles, handheld, and mobile devices (DGEI 2013). The concept of digital games embraces this technological diversity. In contrast with terms such as "video games" or "computer games," it does not refer to a particular device on which a digital game can be played. The common factor is that digital games are fundamentally produced, distributed, and exhibited using digital technologies.

Gamification has been defined as the use of game design elements in nongame contexts and activities (Deterding et al. 2011), which often aim to change attitudes and behaviors (Prandi et al. 2015). Using game-based mechanics, aesthetics and game thinking to engage people, motivate action, solve problems, and promote learning (Kapp et al. 2013; Kapp 2015), i.e., employing awards, ranks during missions, or leaderboards to encourage active engagement during an activity, e.g., health fitness tracking or e-learning during an online course. Thus, gamification uses parts of games but is not a complete game.

Serious games are full-fledged games created for transferring knowledge (Ritterfeld et al. 2009), teaching skills, and raising awareness concerning certain topics for nonentertainment purposes (Deterding et al. 2011). Essentially is a mental contest, played with a computer in accordance with specific rules, that uses entertainment to further government or corporate training, education, health, public policy, and strategic communication objectives (Zyda 2005).

Introduction

The appeal of *mixed reality* (MR) digital games arouses interest among researchers and education specialists who since their recent proliferation have been trying to introduce their motivating

potential in learning contexts. Previous work in this field has been focusing on whether digital games can, via novel presence (feeling of "being and doing there" in a virtual or augmented world) and MR gamification (dynamics, mechanics, components), support and foster future learning and teaching, to address a wide variety and variation of educational contexts. The final aim is to provide informal, nonformal, as well as formal learning for their end users.

This entry aims to highlight their main conceptual differences and key indicative applications and challenges across the mixed reality and learning aims.

Related Ecosystem Definitions and Key Application Areas

The concept of "*presence"* refers to the phenomenon of behaving and feeling as if we are in the virtual world created by computer displays (Sanchez-Vives 2005). "Presence is an incredibly powerful sensation, and it's unique to VR; there's no way to create it in any other medium. Most people find it to be kind of magical" It is not the same as "immersion," where the user is simply surrounded by digital screens (Abrash 2014). Presence is a key term that next-generation of serious-games will need to take into careful consideration to be successful.

Mixed reality (MR) has been defined as a continuum of technologies that include both virtual reality (VR) (fully substitute reality with a virtual 3D world) as well as augmented reality (AR) (supplements reality by blending virtual and real elements with the use of special displays) (Azuma et al. 2001).

Simulation is a realistic, controlled-risk environment, where learners can practice behaviors and experience the impacts of decisions. Simulations are designed to be realistic representations of real-world environments, events, and processes, whereas games on the other hand may or may not reflect the reality. Hence, Simulation + Gamification = Game (Kapp et al. 2013).

Digital Games for Empowerment and Inclusion (DGEI) are Digital games for nonleisure purposes used in specific contexts so that they can empower individuals and communities in ways that lead to social inclusion (Misuraca 2012).

Interactive Learning Events (ILEs) is a term used to include games, gamification, and simulation (Kapp et al. 2013).

Informal learning: Learning without the intention to learn and without actual planning of learning activities. Sometimes also referred to as experiential or accidental learning.

Formal learning: Learning as an intended and planned activity taking place in an organizational context.

Nonformal learning: Learning as a result of planned general activities in which participants can learn both intentionally and unintentionally (Misuraca 2012; Centeno 2013).

Mixed Reality Serious Games and Gamification (MRSG) is used about any kind of serious game, simulation, or gamified process for learning in mixed reality featuring presence, natural interaction, and the suite of the novel MR technologies, MR gesture-based and game-based learning (Zikas et al. 2016).

Indicative nonentertainment themes of serious games and gamification include multitude areas from general education and training (Magnenat-Thalmann et al. 2009) to cultural heritage (Anderson et al. 2009; Kateros et al. 2015; Ioannides et al. 2017), health and surgical training (de Ribaupierre et al. 2014; Papagiannakis et al. 2018), and inclusive well-being (Brooks et al. 2014).

Challenges

One of the main challenges for the next-generation of gamified simulations and serious games involves answering the key research question on *how allow the learners and teachers to experience the feeling of "presence" under a novel MR educational learning framework*, in both virtual reality (VR) as well as augmented reality (AR) formal, nonformal, and informal learning environments. The former (VR) allows for the unique feeling of "being there" and "doing

there" in the virtual world, that will be transforming the overall game-based learning experience, via latest innovations as well as recent progress in low-cost h/w head mounted displays (HMDs). The latter (AR) blends real and virtual elements so that the 3D virtual element is registered accurately in the real world and interacted freely by the learner via various mobile displays, including smart glasses, natural, gesture-based interaction (mobile RGB and RGB-D), MR virtual characters (Vaccheti et al 2004, Magnenat-Thalmann et al. 2009; Jung et al. 2011), and gamified learning processes (Sawyer 2002; Misuraca 2012; Centeno 2013).

Another main challenge for serious-games and gamification involves user-performance metrics, characterization of the player's activity, and better integration of assessment and user analytics in games (Bellotti et al. 2013). "[Serious games] will not grow as an industry unless the learning experience is definable, quantifiable and measurable. Assessment is the future of serious games" (Ritterfeld et al. 2009). In MR, this challenge requires significant future research, but it can be aided by the fact that the end-user position, orientation, gaze, gestures, and actions can be fully tracked and recorded in VR/AR.

Conclusion

In this entry, we have provided clear definitions and latest bibliographical references for the terms serious games, gamification, simulations, digital games, and related terminology suitable for mixed reality continuum. Moreover, we have provided key future challenges that their application in the mixed reality continuum poses.

Definition

The term gamification originated in 2008 and became a part of the game design and digital media design industry lexicon in late 2010. Gamification involves using elements found in game design and applying them to contexts outside game design. A social robot has two parts: a physical presence that interacts with people and a cyberphysical system that is connected to cloud services. Social robots can be designed to behave like humans in limited ways. By using sensors, actuators, and internal systems to speak, make gestures, move, make eye contact, change color, and generate sounds, social robots can demonstrate emotions like joy, sadness, and boredom.

Introduction

Gamification and social robots describe the combination of these two elements to increase levels of motivation and engagement in the first instance, and increase adoption intentions and positive perceptions in the second. Since both gamification and robot design elements – as separate paradigms – have been shown to affect human attitude, researchers believe that the combination of the two paradigms will have a stronger effect on human behavior and attitude.

Social Robot Gamification

The combination of gamification and social robots was attempted in an educational context to increase engagement, motivation, and enthusiasm in self-learning and teacher-led environments (Alsebayel and Berri 2019; Donnermann et al. 2021). Education is a major area used to study the effects of gamification, and research has demonstrated that gamification has a positive influence on students and the learning experience (Hakulinen et al. 2015).

Gamification Elements

In educational environments, four game elements are particularly important in the gamification context: (1) points, (2) badges, (3) levels, and (4) leaderboards.

Points are the foundation of all games. In the gamification educational context, these elements provide feedback for good conduct and report student progress (Sailer et al. 2017).

Badges are realized achievements. It consists of a name, an icon (e.g., an image of a gold cup, medal, or other award), and an achievement description (Hamari and Eranti 2011). Badges give positive feedback and mark work accomplishments – just like points. They also can increase engagement by motivating players to develop game and/or level objectives.

Levels. The three important level types in gamified systems are the following: (1) game levels, which gradually rise in difficulty; (2) playing levels, which is a level a player may select; and (3) player levels, which can be attained after the player gains enough experience points. Achieving a new level in education gamification systems is used as a reward for learners that persevered with assignments and tasks (Nah et al. 2014).

Leaderboards show basic, similar achievements where users can compare their performances, points, and badges.

Social Robot Options

The suggested role a social robot should play in gamification systems is that of a tutor. This is based on the ideas found in self-determination theory (Donnermann et al. 2021). Social robots that are suitable for this role can be purchased commercially or custom designed. The type of robot used in the gamification system depends on the rationale for its use.

Commercially available social robots may have a significantly larger feature set than a custom-built equivalent. One example is the type of expressions a commercially built robot can express and detect in humans. Depending on the make, robots such as Reeti, Nao, and Pepper may have faces, heads, eyes, hands, or legs that possess high degrees of motion. Built-in text-to-speech and voice recognition capabilities enable the robot to read prescripted text, ask questions, and understand the learner's response. These types of robots can also announce achievements and learner points, which is more interactive and engaging than simply having such information displayed in text form on the computer screen. Additionally, before entering the market, commercially available social robots undergo multiple HRI studies in settings that reflect target use cases like elder care, education, and healthcare. This level of testing assures researchers that the social robot can reliably function in similar settings. This allows researchers to focus on higher-level social interactions in their studies including the robot's effect on motivation, engagement, and enthusiasm in learners instead of lower-level interactions such as interface interaction, perception, and user response.

Custom-built social robots. In the study by Alsebayel and Berri (2019), the custom-built social robot was integrated with the gamification system. The robot had three emotional expressions: happy, sad, and resting. It could also blink its eyes and move its head. Given the reduced features and capabilities typical of custom-built robots, their use should be constrained in gamification and social robot studies. Examples of when to use a custom-built social robot may include the following: the need for local or regional accents, parochial appearances, or traditions that are integral to the learner's experience.

Social Robot Gamification Configurations

There are three possible gamification and social robot configurations. Two of these configurations have been used in the literature by Donnermann et al. (2021) and Alsebayel and Berri (2019). However, no work has been done to date using the third configuration. Details on the three configurations follow.

Robot not integrated with the gamification system. In this configuration, the social robot is used with the gamification system, but there is no integration of the robot with the gamification system. Such a configuration allows researchers to investigate the effect the social robot and the gamification system have on enthusiasm,

motivation, and attention as separate, and then as combined systems. However, a potential shortcoming of this configuration is that because the robot and the gamification system are not tightly integrated, navigating the systems may become challenging for the learner when both are in use. Donnerman et al. (2021) reported the unexpected result of increased distraction when both systems were in use.

Robot integrated with the game in the gamification system. In this configuration, the robot is integrated with the game that runs within the gamification system. The degree of integration is limited to data sharing, where the robot acted as an embodied user interface that indicated whether the user's response was right or wrong. The robot possessed no ability to detect human expression, and no other social factors were captured or used to affect the game. The game itself kept track of the correct responses and provided opportunities for the learner to correct their mistakes. There were no other gamification elements in the system beyond score keeping and game levels.

Robot embodies the gamification system. To date, no research has been done using this configuration. As a result, there are many research questions, including:

(i) To what degree should the robot embody the gamification system?
(ii) What gamification elements should be implemented?
(iii) How should the robot's appearance and behavior reflect the gamification elements?
(iv) How do these factors affect learner motivation, enthusiasm, and engagement?

Conclusion and Discussion

Research in gamification and social robots as a method for increasing motivation, engagement, and enthusiasm of learners in an educational setting has so far produced inconclusive results. This is because there are few studies done in the area to date. Besides replicating, or repeating, experiments were done in Alsebayel and Berri (2019) and Donnermann et al. (2021), whose work was done using two of the three gamification configurations: (i) robot combined but not integrated with the gamification system and (ii) robot connected to the game in the gamification system. There are many opportunities for research to be done in the third configuration option where the social robot embodies the gamified system.

Synonyms

Dark side of gamification; Ethical issues in gamification; Ethics in gamification

Definitions

Gamification ethics refers to the study and understanding of right and wrong conducts by or with gamified solutions. As gamification taps into the natural playfulness of human beings, ethical issues are prevalent and must be considered by the developers.

Introduction

The term "gamification" usually refers to applying game design elements into nongame contexts (Deterding et al. 2011). Typically, it is used to improve the motivation and performance of the players to tasks like learning, well-being, rehabilitation, or work efficiency. For example, Hamari et al. (2014) show how gamification can improve the players' motivation in possibly arduous and boring tasks.

The road to gamified solutions has often been paved with good intentions where designers, developers, and funders are aiming at improving the players' quality of life. However, even projects that have been developed with good intentions may end up in creating ethically questionable or even clearly morally wrong solutions. This reminds of the statement attributed to Albert Einstein according to which if he would have known how atomic power was to be utilized, he would have preferred to become a watchmaker instead of a scientist.

As gamification touches the very basics of the playful nature of humanity, the designers and developers of gamified solutions can either through pure mistakes or with evil intentions create products and services which either endanger or worsen the condition of the players, the environment, or the society. Whereas it is hard to enlighten developers with bad intentions, it is crucial for the developers of gamified solutions with good intentions to understand the ethical challenges inherent in the used techniques.

The main things for a developer to keep in mind regarding ethics, on top of their own intention – which of course ought to be the good of the stakeholders of the application – are that the applications are built in a just manner and that the consequences benefit the client, the users, and the targets of the systems being designed (Moor 1999). Even though most developers consider themselves to be good people, as Don Gotterbarn always reminds us, they should also be aware that if they do not actively look after their character traits related to their work in a virtuous manner, they do not always act as they ought.

Based on the theoretical ethical principles, applied ethics aims at tackling a certain area. The ethical questions raised by gamification techniques have only recently gained interest with the works of Bui et al. (2015), Hyrynsalmi et al. (2017a, b), Kim and Werbach (2016), and Sicart (2015). The field remains still largely unexplored, yet further studies are published with an increasing pace.

While our aim here is to provide a broad overview of ethical problems of gamification, this is not a comprehensive list of all possible issues. As both the field and the techniques are still evolving, new ethical questions are expected to pop up and some of the older topics will become outdated with the new systems.

Our intention in this entry is to give an introduction to the ethical problems present in gamification. In the subsequent sections, we divide gamification ethics into three broad groups:

ethical problems related to the *design* of gamification, ethical problems related to the *technology* used in implementing gamified systems, and ethical problems related to the *data* utilized by gamified systems.

Issues on Gamification Design

The design phase includes activities typically carried out before and during the implementation of a gamified system. While gamification aims at improving the players' interests on virtuous issues and tasks, there are examples of using it for malevolent purposes such as stealing or damaging CCTV cameras or even prompting players to commit suicide (Hyrynsalmi et al. 2017b). Omitting such extreme examples, there are, however, solutions that are either legal but questionable or that have been developed with good intentions whereas their consequences are ethically questionable. For an overly simplified example, a gamified solution for a nurse, paramedic, or firefighter could, in theory, improve their job satisfaction; however, every second spent on secondary purposes, such as gaining points in a gamified environment could, literally, endanger someone's life or property in these kinds of contexts. The basic design question one should always ask first is: does gamification work in this particular context?

From the perspective of gamification design, we can recognize two general groups considering the implications on an individual person and on the impacts on a society.

Personal

Gamification overloading is a rarely addressed topic in design. An average player is likely advance only in few different games at the same time. The average player does not play several massively multiplayer online games simultaneously due to the cognitive burden caused by keeping up several different tasks, stories, and game mechanisms. The same cognitive limits apply also to gamified solutions. Would an average gamification player be able to simultaneously keep up with gamified electricity saving, physical exercise, and educational solutions? Thus, designers should also ask whether gamification brings long-lasting value in the particular context or whether it would turn against its objective due to potential overload.

Individual players cannot be handled as a homogeneous group. For instance, let us consider the case of an individual who is a game addict. Should he or she be exposed at his or her workplace to a gamified system? If not, would he or she be in a different, possibly weaker position than others? A similar kind of though experiment could be carried out with underaged pupils (e.g., educational gamification), elderly, or cognitively challenged users.

Societal

Employees can deliberately fake information on gamified system, for example, to use the leaderboard to advance their position in salary negotiations (Callan et al. 2015). Cheating in general is a likely problem, if the gamified system has real-world benefits that can be gained. Moreover, tapping into the competitive drive of the players of a gamified system can have destructive consequences on the work environment as the competition leaks from gamification into the real world.

Technology-savvy younger players might have an advantage in using gamification because of their familiarity of game mechanics from entertainment games.

Putting the participants in an equal starting position is a hard problem to solve, which is tackled by game balancing in game design (Adams 2014, pp. 403–405). A balanced game is fair, meaning that all players have an equal chance of winning at the start, and it should be appropriately challenging (i.e., not too hard nor too easy) for the players. The skill in the actual task of the player, rather than in the game created on top of the tasks solved through gamification, should be the most important factor in determining the player's success.

Furthermore, it is possible that the setup or the story in a gamified system favors a majority of the players, ignoring the (gender or ethnic) minorities' interests or values. In a workplace situation,

this might even enforce the existing and possibly hidden attitudes and prejudices.

The motivation behind gamification can be, in some cases, hidden from its players. For example, the design of the game *Ingress* – developed by Niantic, a company spun off from Google – is assumed to have originally been motivated to gather location information to improve Google's map services. From this commercially motivated example, we can draw a parallel to Sesame Credit – developed (via affiliates) by the Chinese on-line marketing conglomerate Alibaba and the Chinese government – where the design motivation is, at the same time, both commercial and political.

If gamification is used for political purposes, it opens the possibility for using it as a tool for propaganda and surveillance. The ethical implications of this are manifold: conventional values such as "harmony" in the society are typically enforced, a lack of revolutionary and thus society-enhancing ideas can follow. And, of course, there are clear risks for the privacy of the players. Just think of Stasi (*Staatssicherheitsdienst*) or similar organization gamifying their surveillance of the citizens, or gamifying catching illegal immigrants entering the country – one can be of the opinion that illegal immigrants ought not to enter the country, but would it really be a good idea to make this kinds of consequences to actual living, breathing, and feeling human beings into a *game*?

Compromising the Underlying Technology

The technology used in gamification should protect the players' sensitive information and allow them to decide how the information is used (cf. Lahtiranta et al. 2017). Moreover, it should provide a fair playing field for players and prevent any kind of cheating. These attributes can be compromised by attacks utilizing either technical or social weaknesses. For example, passwords can be stolen by cracking them (technical attack) or pretending to be administrator and asking the players to give their passwords (social engineering attack).

The technical attacks can be directed to the clients, the servers, or the network connecting them (Smed and Hakonen 2017, pp. 290–291). An attack can take place over (e.g., reading pixel values from the user interface), under (e.g., hacking a driver), or in the client (e.g., altering the code in the memory). Apart from physical attacks (e.g., theft), servers are vulnerable to network attacks (e.g., IP spoofing or denial-of-service attacks). Network communication can be compromised by tampering the packets (e.g., intercepting or replicating them or forging their payload data).

The social engineering attacks can include, but are not limited, to blackmail, using the gullibility of the other users, gaining access through pretending to be a superuser – for some reason without superuser access – or bribing others either with joint sharing of results (cooperating against others unfairly) or paying smaller amounts for greater gains (Mitnick and Simon 2003).

The motivation behind the attacks on games can stem from different sources (Consalvo 2007) but broadly speaking, we can recognize three areas:

- Enhancing the gameplay motivated by, for example, lack of skill or time or by boredom
- Playing with the game system to explore and experiment, extend the lifespan of the game, or creating new ways to play
- Extra-game factors such as money, fame, vandalism, or nonconformity

Although any breach of the information security can have severe repercussions to the player, the motivation plays an important role in discerning the possible ethical consequences. Players wanting to enhance they gameplay will, naturally, increase inequality among the other players. A similar situation may ensue even if the players are playing with the gamified system, although their motivation is not directed against the other participants. The biggest threat comes from the last group. When extra-game factors are included,

the other participants will be become expandable and just means-to-an-end.

Use and Scope of the Gamified Data

Gamified solutions generate personal data from the players' personal interests, actions, and habits. Thus, the environment where the gamified solutions are used affects the ethical questions of gamification. In the following, we have identified five environments where intentions to gamify as well as ethical questions differ: healthcare, work life, government, school, and leisure systems.

Healthcare

The healthcare sector is actively looking for ways to improve people's health behavior using technology, and gamification is seen as a promising opportunity. It is possible to imagine a gamified healthcare system provided by public healthcare that drives for a lifestyle change (e.g., to get rid of intoxicants, to get more exercise, or to lead a generally medically reasonable life). We are not criticizing gamification itself as it could be a good tool for many people to achieve these goals, but there are some risks we want to point out that are involved.

The primary concern is that health is an area of life where people can be highly vulnerable, because for many, it is not possible to choose the services they would want, for example, due to financial or geographical limitations. The secondary concerns relate to the data produced with these kinds of solutions: personal health records of any kind are extremely private.

There is a risk that the user could lose the control over the information gathered by the gamified system, if it is also used for larger healthcare purposes. There is a drive to collect medical information for research purposes, which is usually done in good faith. However, we know from examples that the genetic information of entire countries has become tradeable goods, in which individuals have lost control over their data.

Healthcare gamification drives towards a biomedically desirable lifestyle. The personal experience of health, however, is not a biomedical experience but rather an existential experience; what could be called homelike-being-in-the-world (Svenaeus 2001). Hence, what people experience as good health varies from person to person and depends on their personal goals and desires in life.

Work Life

The current work-life environment – riddled with financial crises, work automation, competition in employment – leaves many employees with no possibility to change their employer. Consequently, we are more and more attached to our current employment, and if the environment is gamified, a gamified system in the workplace could force us in an ever-increasing competition against one another. This would turn us into an exploitable "standing reserve" for corporate purposes that would take away considerable parts of our power over our own lives, creating new "rules" and endangering the authentic (self-owned) being in the context of working life (Heidegger 1977).

Nevertheless, there are many employers who willingly take new technologies into work environments with the aim of helping employees to be empowered at work. Such solutions can, for example, be linked to job satisfaction, feedback, or suggestions for improvement. In such data-driven gamified solutions, particular care should be taken to keep hidden the unique characteristics that would help to identify individuals.

Government

Governmental information systems are the tools that are used by government and citizens forming a part of how our society is working and communicating. When thinking about the gamification of government systems, one has to understand that systems can be such that citizens are obligated to use them. Since the idea of gamification is to change people's behavior through information collected through gamification, there is a risk that individuality will be lost and the demand for being an "average" citizen will increase. This should be avoided as it causes citizens to lose their individual life goals and only become

statistics in a government plan; after all, we do have our own desires, hopes, and fears that should be valuable in and of themselves.

In addition, citizens are unlikely to have the ability to know – and even less to control – who uses their information and for what purposes. Another example of problems in gamification is that it could be used to "activate" unemployed citizens. It is often claimed that unemployed people should perform some activities to get their unemployment benefits. However, gamification does not create new jobs but easily becomes just one more duty for those weakest in our society; this does not help them but highlights the lack of power of the unemployed. Since our governmental systems are a vital part of our modern society, it is important to ensure that the privacy and liberties of citizens are secured by the government; otherwise, we risk the foundations and justification of democratic society.

School

For younger people, there is a risk that they may not have the capacity to claim or the will to demand different solutions. When thinking of gamification, pupils lack the power to choose what is used for teaching. This underlines the need to protect their privacy and other related rights, as they have no judicial or practical means to control how gamification and the information collected from them affect them now or later in life.

When we add gamification in education, there is a risk that the division between "good" and "bad" pupils will be emphasized and, as a consequence, the result may be that inequality between children grows. Since pupils do not yet have full rights or responsibilities as adults do, it is our responsibility to safeguard their right and govern their rights as long as they are considered to be equal members of the society. In the case of young people, this means that in adulthood they can decide that they do not want their personal and/or identifiable information to be used; they need to have the right to prevent the use of it and even to destroy information considering them, if they so decide.

Leisure

Gamified leisure is a different matter altogether. Although gamified systems may have an impact on who and what we are in our free time – unless there is a monopoly (or oligopoly) of systems to use – we can always opt out as long as we understand the changes to us the system can make. Nevertheless, we must at least be able to remove our data from the system we have used or tried out, which is a minimum of control requirement.

For instance, we could use sports applications such as heart rate monitors, which these days provided a wealth of additional applications from GPS to following our sleep and beyond. These applications use our data as well as the data of others and gamify the exercise experience. The "100 percent" is likely to be defined, at least in part, by utilizing aggregated user data. The user can, if they want, stop using the system. However, they still have no control over the data already collected, and it can later be used by the application developers as they please.

Summary

This entry highlighted ethical issues embodied in the use of gamification tools and techniques. As gamification touches on the very basic nature of humans, it is important for the designers and developers of gamified solutions to understand the ethical ramifications of the decisions on design, technology, and data.

While our aim was to bring gamification ethics into public discussion and extent the awareness of possible pitfalls, we are not advocating avoiding gamified solutions altogether. Rather, we encourage designers, developers, and funders to actively utilize the best of gamification techniques for the best of humankind while still minding the ethical considerations.

Definition

Gamification is generally defined as the use of game design elements in non-gaming contexts. Crowdsourcing is understood as the process of obtaining content and/or services by involving contributions from a large group of people, in particular from an online community. The use of gamification techniques in crowdsourcing applications is mainly due to the need of involving and engaging more users and of improving their experience.

Introduction

In recent years, new forms of game and game technologies have emerged in the fields of industry and academia research. In particular, it is evident in the growth of serious and pervasive games. In this context, a new trend, called "gamification," has reached and won many sectors, including the business and the marketing domains (Seaborn and Fels 2015). Such a new trend essentially uses game design and elements with the aim of improving users' experience and increasing users' involvement in services and applications which are not games (Deterding et al. 2011). Its goal is explicitly different from the merely users' entertainment.

It is worth noting that gamification is not a new issue, but it can go back to marketing activities and techniques (i.e., points cards and rewards memberships), usually exploited to engage clients, by creating or enforcing loyalty in a product or in a brand (Zichermann and Linder 2010). Current technologies, together with the widespread and massive use of social media and mobile devices, can be identified as joining causes which are facilitating the diffusion and adoption of gamification techniques in so many and different contexts (Seaborn and Fels 2015).

The first successful example of gamified service has been Foursquare. Starting from such an experience, other several gamified applications were born, exploiting game elements together with interactive design and digital marketing issues (Zichermann and Linder 2010). At the same time, gamification has been recognized as a key issue to support and incentive massive collaboration from and among users (McGonigal 2011).

The goal of this work is to define gamification, by summarizing game design elements which characterize it and by describing how such elements can be exploited in crowdsourcing systems, improving crowd's experience and involvement.

The remainder of the work is organized as follows. The "Gamification" section describes the introduction of the term, the game elements which characterize it, and players' motivations. The section entitled "Gamification in Crowdsourcing Systems and Social Media" presents some examples of crowdsourcing applications which benefit from the use of gamification. Finally "Conclusion" closes the paper.

Gamification

The word "gamification" has been used for the first time in 2010, when Jesse Schell gave a talk entitled "Design Outside the Box" Schell (2010): he foresaw the use of game mechanisms with the aim of increasing users' engagement in non-gaming contexts (Bouça 2012). After that, "gamification" has become a buzz and trendy word (Deterding et al. 2011), and its techniques have been applied in different contexts and applications: from education (Foster et al. 2012) to wellness and health (Cafazzo et al. 2012), from marketing (Downes-LeGuin et al. 2012) to sustainability (Liu et al. 2011), etc.

Actually, the use of game design, elements, and mechanisms in non-gaming contexts is an old topic: in human-computer interaction, the idea of exploiting enjoyable interfaces from games went back to the 1980s (Malone 1982). More recently, several works have been inspired by game design in reaching the goal of identifying principles, patterns, and elements that might provide joy of use and enhancing the motivational affordances of computer-supported collaborative work (Jung 2010), on the basis of researches on the motivational psychology of video games (Ryan and Deci 2000).

Several works propose some alternative terms for gamification (Seaborn and Fels 2015; Deterding et al. 2011), including "ludification" (Bouça 2012), "behavioral games," "serious games," and of similar concepts, such as "games with a purpose" (von Ahn 2006), "pervasive games," and "augmented reality games."

Even if the gamification concepts and techniques, as well as the psychological and sociological users' motivation, have been studied and applied in several contexts (Deterding et al. 2011), a lot of questions are still open, such as: "how many game elements does it take until a gamified system becomes a game?" (Seaborn and

Fels 2015). In this sense, the term "gamification" can also be used to describe the transformation of an existing system into a game: gaming elements and concepts could be inserted into a system (enhancing existing elements) or the system could be converted into a game (Mekler et al. 2013).

Game Design Elements

Seaborn and Fels (2015) and Mekler et al. (2013) have analyzed several works, identifying main game elements which are exploited in gamified systems. A list of such elements follows:

- *Points* (*experience points*, *score*): they are numerical units which indicate users' progress.
- *Badges* (*trophies*): they are visual icons which indicate users' achievements.
- *Leaderboards* (*rankings*, *scoreboards*): they display ranks for comparison among users.
- *Progression* (*leveling*, *level up*): they are milestones which indicate users' progress.
- *Status* (*title*, *ranks*): they are textual names which indicate users' progress.
- *Levels* (*stages*, *areas*, *worlds*): they indicate increasingly difficult environments.
- *Rewards* (*incentives*, *prizes*, *gifts*): they indicate tangible, desirable items the users aim to obtain.
- *Roles* (*class*, *character*): they indicate role-playing elements of character.

Game design issues in systems applying gamification have been analyzed by Seaborn and Fels (2015) and Deterding et al. (2011) and can be listed as follows:

- *Game interface design patterns*: they can be identified with common, successful interaction design components and design solutions for a known problem in a context, including prototypical implementations. Some examples of game elements based on this issue are badges, leaderboards, and levels.
- *Game design patterns and mechanisms*: they are commonly derived from traditional game design, as, for example, time constraints, limited resources, and turns.
- *Game design principles and heuristics*: they can be identified with evaluative guidelines to approach a design problem or analyze a given design solution. Some examples are enduring play, clear goals, and varieties of game styles.
- *Game models*: they can be understood as conceptual models of the components of games or game experiences. Some examples are challenges, fantasy, curiosity, game design atoms, and core elements of the gaming experience.

Players' Motivations

Game design mechanics and dynamics are mainly based on users' motivations (Blohm and Leimeister 2013), which can be driven by intrinsic and/or extrinsic motivators. These psychological terms describe different ways in which people can "be moved to do something" (Ryan and Deci 2000). On the one hand, intrinsic motivation is defined as "the doing of an activity for its inherent satisfactions rather than for some separable consequence." When intrinsically motivated, a person acts for the fun or challenge entailed rather than because of external prods, pressures, or rewards (Blohm and Leimeister 2013). On the other hand, extrinsic motivation "is a construct that pertains whenever an activity is done in order to attain some separable outcome," just like a reward (Mekler et al. 2013). In this sense, gamification is based on the extrinsic motivation, which can be effective in changing behavior and creating loyalty in users (Bouça 2012).

In Blohm and Leimeister (2013), motivations are associated to game design mechanics and dynamics as follows:

- *Intellectual curiosity*: it has been associated with documentation of behavior (as game mechanics) and exploration (as game dynamics).
- *Achievement*: it has been associated with scoring systems, badges, and trophies (as game mechanics) and collection (as game dynamics).
- *Social recognition*: it has been associated with rankings, levels, reputations (as game mechanics), and competition and acquisition of status (as game dynamics).

- *Social exchange*: it has been associated with group tasks (as game mechanics) and collaboration (as game dynamics).
- *Cognitive stimulation*: it has been associated with time pressure, tasks, and quests (as game mechanics) and challenge (as game dynamics).
- *Self-determination*: it has been associated with avatars, virtual worlds, and virtual trade (as game mechanics) and development and organization (as game dynamics).

Gamification in Crowdsourcing Systems and Social Media

Nowadays, crowdsourcing is commonly adopted by several systems, with the aim of performing distributed and collaborative tasks (Estellés-Arolas and González-Ladrón-de-Guevara 2012). Some of these projects exploit human abilities when they can overcome and solve problems impossible to be completed by a computer, such as the annotation and/or tagging of images, videos, or web and social media content. As an example, the reCAPTCHA project (von Ahn et al. 2008) takes advantage of the crowd in solving CAPTCHAs to help to digitalize books and newspaper, while the Dotsub platform (http://dotsub.com) aims to collect video captions from the crowd.

Several crowdsourcing systems apply different gamification techniques with different aims and contexts. Some examples are presented in the following.

Gamification in Multimedia Tagging and Captioning Systems

A famous project based on random web image labeling is the ESP game (von Ahn and Dabbish 2004), an online two-player game with the goal of guessing what label the other player would give to the displayed image. This is one of the first examples of game with a purpose (GWAP) performing useful tasks by means of crowdsourcing. The gaming elements introduced are points, time constraints, comparison between the players (as leaderboard), and intermediate results (as progress). ESP game evaluations show that the gamification techniques reached the main goals of engaging users and increasing the user-generated content.

Labeling images is the aim of Mekler et al. (2013) too. The authors applied different gamification strategies to an already existing image tagging platform and involved participants, asking them to enter labels related to a shown image. The authors developed different versions of the same system, as many as the game elements they applied (points, leaderboard, and levels). Then, they have compared such versions together with a non-gamified one. The tests show that those gamification elements concur in enhancing users' performance, promoting a specific user's behavior.

People with special needs are taken into account by Kacorri et al. (2014), where the authors proposed the adoption of game elements in crowdsourced video captioning, so as to increase video accessibility for deaf and hard-of-hearing users, providing benefits also to second-language learners. The authors exploited an already existing collaborative caption editing system, which has been equipped with points and time constraints. A pilot experiment showed the feasibility and the effectiveness of the proposed gamification.

Gamification in Learning Language and Translation Systems

A very famous project which exploits crowdsourcing and gamification in the same translation system is Duolingo (https://www.duolingo.com/). Duolingo is a free language-learning and crowdsourced text translation platform. Engaged users learn a language, progressing through the lessons, and help to translate any web content (including images, video, tweets, and so on) into their native language, at the same time. Game elements are applied in the learning part of Duolingo: from points to time constraints and from levels to leaderboard.

The aim of AlRouqi and Al-Khalifa (2014) is the translation (also in the image-to-text form) of Arabic documents, so as to make them more accessible, even to those users with low vision.

The authors proposed a mobile crowdsourcing system, where they have applied gamification mechanisms (in particular points, leaderboard, and time constraints).

Liu et al. (2011) have designed and developed UbiAsk, a mobile crowdsourcing application for image-to-text translation. UbiAsk exploits points, status, badges, and leaderboard so as to encourage participants to tag and translate images provided by foreign travelers, so as to support their language comprehension. Experiments were conducted and confirm an increasing involvement of the participants when gamification strategies are applied.

Gamification in Location-Based Systems

Foursquare (http://www.foursquare.com/) represents the most popular example of gamification in crowdsourcing systems and social media (Bouça 2012). It is a location-based mobile app, which lets the users provide information about their location, about suggestions related to a certain location, and so on. It applies most of the common game elements typically involved in gamified apps: points, badges, leaderboards, and incentives (Zichermann and Cunningham 2011). Points are used to track game status and feedback, badges to set goals, leaderboards to add a competitive layer, and incentives represent the reward.

Other well-known examples are Waze and Swarm. Waze is a GPS-based geographical navigation application for smartphones with GPS support, which provides information and user-generated content about travel times and route details, downloading location-dependent information over mobile networks. Waze uses gamification (points) to engage users and encourage them to provide more information. Waze also offers points for traffic or road hazard reports, which can be used to change the users' avatar and to increase users' status in the community (https://www.waze.com/).

Swarm is a mobile app that lets users share their locations within their social network (https://www.swarmapp.com/). It is a spin-off of the older Foursquare, which supports users in checking in to a given location, as well as making future plans with friends and seeing who is nearby. Swarm exploits badges, points, and competition against all other users of the service to improve their level, becoming the "mayor" of a location.

Gamification has also been applied in location-based systems with specific purposes, such as supporting citizens with special needs in urban environments (Palazzi et al. 2011; Prandi et al. 2015; Salomoni et al. 2015). While the former exploits points and rewards, in the latter the game scope is totally different from collecting data, but data gathering permits to gain weapons which can be used in zombie hunting.

Conclusion

In this work we have defined the term "gamification," which identifies a still emerging but significant trend related to serious games and games with a purpose. We have identified main game design elements and users' motivations at basis of gamification. Moreover, we have described how gamification techniques can be applied in crowdsourcing systems, by presenting some examples where gamification reaches the goals of engaging users, involving them in providing user-generated content. In many contexts and systems, gamification is still an ongoing process.

Game mechanics; Gamified experiences

Definition

Gamification is the implementation of game mechanics for use in areas typically not associated with gaming (Kadison 2015). Gamification engages users and solves problems through use of game-thinking and game mechanics processes (Zichermann and Cunningham 2011). The difference between gamification and game play (i.e., physical fitness games versus candy clearing games) is that with gamification the creator is looking to solve a real-world problem (Kim 2015a). For example, applications such as wrist pedometers encourage individuals to get in shape through gamification and works to solve the real-world problem of weight gain. Applications aimed at learning a second language encourage individuals to become bilingual and solves the real-world problem of limited bilingual speakers and services available.

Introduction

In today's society, gaming culture and use of modern digital media devices has influenced the casual user by assisting in solving real-world problems through the mode of fun and gamification (Kim 2015a). The scope of gamification has been implemented in businesses from health and fitness industries, to retail marketing, and to the education and learning industries. In 2013, the gamification market was worth an estimated $421.3 million and is expected to grow to $5.502 billion by 2018 (Gamification Market Worth nd). This would give the industry a compound annual growth rate of 67.1 %! It would appear the use of gamification is lucrative and will only continue to grow based on the projected increase in worth.

Over recent years, society has witnessed the ever-growing influence and acceptance of technology and digital game concepts being incorporated in our day-to-day lives. The use of these "gamification concepts" include various psychological approaches regarding the use of technology to aid in evoking, motivating, influencing behavior and even changing the habits of the user (Kim 2015a).

Using today's technology, users have begun to incorporate game-like point-based methods to affect everything from shopping habits, education patterns, and even their physical and mental personal health. With the ever-growing availability of technologies such as wrist pedometers and smart watches, to the language learning applications, we as a society are seemingly thriving more and more on technology and gamification to influence our everyday lives.

What drives us as a society to explore and accept these "seemingly empty" point-based applications that influence our actions so strongly? What internal rewards do we receive? What constructs are affected by us using gamification in our everyday life? This paper will explore the gamified experience, current research, knowing the player, and implications of gamification on society.

Where Do We Find Gamified Experiences?

Though instituted in the early 2000s, the popularity of gamification has seen a relatively rapid rise

since 2013 (Gamification Market Worth nd). Its initial development and implementation was intended to leverage crowds, process data, and help influence consumer behavior through the implementation of game mechanics (8 Reasons 2014). So where do we find the use of gamification? Many companies over the past few years have implemented the use of gamification to leverage their consumer interaction. The goal of these games is to intrinsically motivate the user and offer increased satisfaction (as the user is able to obtain immediate feedback and set achievable goals), feel optimistic, (encourages self-determination and gives the user a sense of personal achievement), encourage social interaction (through social exchange), and give the user meaning (as they are working toward solving problems) (Blohm and Leimeister 2013).

Gamification is also aimed at increasing mental health. It introduces the idea that the user can be autonomous while being in control and having fun (Blohm and Leimeister 2013). These ideas are based off of the idea of the "fun theory." The fun theory asserts that fun is the easiest way to change behavior for the better (The Fun Theory nd). Gamification can also spark behavioral change. As the individual is engaging in gamification, they are getting positive emotional feedback. This can spark a change in habits or create a new, healthier habit. For example, an application that encourages mindfulness and meditation encourages individuals to increase positive coping skills and is aimed at decreasing symptoms of anxiety. One such application is advertised as a gym membership for the mind and uses game to change an individual's daily habit and routine in order to improve mental health. Consequently, there has been an increasing interest in use of games in child therapy and mental health over the past 10 years (Schaefer and Reid 2000).

Gamification has also broken through into the fitness industry. For example, Nike released an application that sparked two million individuals to burn 68 bn calories (Blohm and Leimeister 2013). There are also other popular fitness applications, which helps the individual track their exercise, sleep, and calorie intake. As the individual increases their steps they are rewarded through badges and encouraging statements. The individual can also interact with their peers and engage in competitions to track their fitness for the day.

Gamification has also impacted the educational and business field. Deloitte (a small company) developed a gamified online training program (Deloitte Leadership Academy) (Kim 2015b). Use of the gamified training program resulted in an increase in amount of time people spent on program and an increase in number of programs completed. This training also showed a 37 % increase in users returning to the site (Kim 2015b).

Colleges are also using the concept of gamification in their orientation to increase engagement. A professor at the University of Michigan went so far as to create his undergraduate class in game form. This gave students the ability to choose their own options to meet the learning goals of the class while getting feedback and being able to join "guilds" in the classroom (Kim 2015b). Bilingual applications have also increased education by creating a fun way for an individual to become bilingual. A study conducted by the City University of New York and University of South Carolina found that 34 h spent on a bilingual application is equivalent to a semester (roughly 11 weeks) of a language at university (DuoLingo 2015). This makes learning free and accessible to anyone with access to this application.

Even the retail industry has seen a rise in gamification experiences. Many credit cards now have offer point systems in which they use rewards such as, travel and consumer products, to entice the consumer to sign up for their credit card (Olenski 2014). In this way, gamification is beneficial for both the industry and the consumer. By participating in the loyalty reward programs, consumers feel that they are getting a "deal" by cashing in points for simply spending their everyday dollar (this gives them the control previously discussed). This gives the consumer multiple reasons to spend money and motivates them in the market place (8 Reasons 2014). This also benefits the credit card companies as they can partner with various retail sponsors so that point users are required to cash in their loyalty points with those vendors. This free advertising is beneficial for the

retail companies and they in turn help sponsor and support use of the specific credit card.

Research and Future Direction

In 2014, 500 Thai consumers were surveyed about the influence of gamification in their everyday lives (Zepeda 2014). The highest age of interest was between 24 and 32 year olds, and 88 % of the 500 consumers surveyed said they would choose to buy brands with a reward point system. In fact 85 % said they would pay more for the product if there was a gamified mechanic involved in the product (Zepeda 2014). With this type of interest it is no surprise that businesses are jumping at the chance to implement game mechanics into their products.

Other research show that child gamers are "letting off steam" in response to problems with friends or parents, with feeling of guilt or frustration in their gameplay (Colwell 2007). There has been an increasing interest and use of games in child therapy over the past 10 years (Schaefer and Reid 2000). Child therapists often times have to carry multiple board games and toys into therapy sessions to engage interactively with their clients. Therapists use play therapy techniques to help children gain emotional trust with them and heal through use of fantasy in which they are able to explore previous trauma or current life stressors in a safe and nonjudgmental environment (Schaefer and Reid 2000). The idea of taking preexisting games and changing the rules is not uncommon. The future of gamification will be incorporating these elements of games for noncommercial use and providing them to doctors and health care professionals in order to better diagnose and treat conditions.

Why Do We Game?

Before we understand the elements of gamification, we must first understand why people play games. The root of most game play is interaction and engagement of the player. Players are often times drawn to gaming as an escape from their world and a therapeutic release. Gaming allows player to not only engage in the game play but also become a bigger part of the games community. In turn subcommunities are formed within these gamified experiences to develop not only a player's social network, but also the player's reputation.

Gamification implements many common game mechanics into non-typical game activities. Badges or rewards, points, level upgrades, leaderboards, and challenges are just a few of the ways companies draw users into utilizing their gamified experience. Using these milestones and badges creates support as individuals use gamification to problem solve ways to accomplish the game's goal (Blohm and Leimeister 2013).

The badging effect promotes player participation by the reward of a graphic icon with any level or point upgrade in the game. By doing so, badging helps members feel more involved in their community (i.e., social support as discussed earlier). Many gamified experiences start their players off with a welcome badge just for downloading their applications. This immediately gives the player a sense of community from the get-go. In turn all badges are typically displayed on the members profile so they may compete against one another.

Point systems are used to help obtain badges. When an application needs to provide the player with a measurement of their accomplishments, they typically are rewarded points. This is typically done by the developers assigning points to common actions such as checking in, miles run, and even comments made on a particular forum. For example, Texas Instruments gives points to their employees who ask and answer questions on their internal forum. The points are, in turn, used to boost an employee's reputation and eventually lead to social and economical promotion within the company.

The driving force behind all gamified experiences is, as mentioned, giving the player a sense of community, autonomy, and control (Blohm and Leimeister 2013). Players are influenced by mechanics like points and badges but other elements need to occur within the game in order to retain players for increased periods of time of the

game experience. Instant feedback and clear goals are two of the most important elements of keeping the user involved within the application. Gamification should be composed of a variety challenging but achievable tasks with compelling outcomes. By retaining players within the gamified applications, users will not only stay involved in the social community created but this will also influence them to bring new players into the social network.

Knowing Your Player

Bartle describes four common types of gamers: killers, socialites, achievers, and explorers (Bartle 2008). Killers focus on winning and direct competition, while socialites focus on developing a network of friends and contacts. Achievers focus on attaining status and achieving goals, while explorers focus on discovering the unknown. Knowing these four types can help industries appeal to various players.

Businesses that wish to bring a gamification experience into their consumer relationship need to be aware of these player types. While focusing on one player type might seem like the most logical step in developing a gamified experience, an experience with a combination of the four player types might be the most impactful way in development and implementation. In doing so, businesses will be able to customize their games and gaming experience to their consumers in very specific ways. It is important that the developing business understand the competitive spectrum of the player when inciting players to interact with their gamified experience. Players do not have to fall into one of Bartle's singular player types but, put simply, their competitiveness must be measured. Caring, collaborative, cordial, competitive, and combative are a few of the player motivation scales (Bartle 2008).

Conclusion and Discussion

In conclusion, the idea of sitting in front of the board game, television with a console system, or an arcade machine to play game has begun to become a thing of the past. The elements of gaming have gone beyond entertainment and found their way into the consumer world. The gamification of modern society really begins to blur the lines of what is considered a game. Most aspects of everyday consumer life are influenced by elements found in games, such as, competition, reputation, and our social network.

What is the future of gamified experiences? As mentioned, the gamified experience has gone beyond the arcade and entered our everyday lives. When does the term "game" become obsolete in our society? Will there ever be a time a place where these elements are simply integrated to all aspects of our everyday routines? In addition, will there be other uses for gamification beyond entertainment and consumerism?

The future of gamification, in my opinion, is to help invoke social change. Current research shows positive mental health benefits in playing commercial-based interactive games. Could these same concepts be spun into gamified experiences to better serve treatment of patients in healthcare? With the increase in interest and use of games in mental health, therapists are able to incorporate gamification into their session to incorporate play therapy techniques to promote healing and behavioral changes. Future implications could include gamification incorporating these elements of games for noncommercial use and providing them to doctors and health care professionals in order to better diagnose and treat conditions. As bilingual applications have done with their applications, the use of gamified experiences within the education industry is just as important. Providing instant, accessible, and efficient motivators of learning will indeed shape the industry for years to come. Physical well being is also increased with use of gamified physical fitness applications. Gamification seems to present a holistic approach as it can incorporate mind and body into its approach. Consumerism will always be a part of this industry and practice, but the more accessible we can make these applications the more beneficial they can become to society.

[2]Arab Open University, Amman, Jordan
[3]Universiti Sultan Zainal Abidin, Gong Badak, Malaysia

Synonyms

Brain control interface; Game control; Human-computer interaction

Definition

A Brain-Computer Interface (BCI) is a device that can obtain all operations of the brain that has become a promising technology in human-computer interaction (HCI). HCI has a clear

primacy in the world of gaming as gamers are one of the largest HCI app subscribers. The human thoughts are transmuted by the brain over brain signals and expressed as an attitude. This process is mainly carried out over brain signals, which are the key component in the electroencephalogram (EEG).

Introduction

The gaming system is the main research trend of HCI, which comes from the widest implementation of games within various fields in this domain. The BCI technique becomes a leading control for the new virtual systems as it provides a direct pathway of communication between the external environment and the users' brains. In 2017 and 2014, Ismahafezi et al. (2017) and Abuhashish et al. (2014) agreed that EEG signals research is a current approach in BCI due to its usability in the HCI field. Therefore, the rapid revolution growth of HCI in the field of gaming using BCI considered a future pursuit. A cheap and easy way to use the BCI device has been developed by Emotiv, which is called EPOC. This device is used without the intervention of tangible senses including hands to control the game; it depends on brain activity that expresses the game player moving control, facial expressions, and emotions. Therefore, there is no need to use sticks, buttons, motion sensors or gyroscopes as in traditional game controllers. To perform as a game controller, the obtained EEG signals need to be interpreted into meaningful instructions in a course that enables easy game playing.

Computer games always have a large market, according to Global Entertainment and Media. BCI Games could be a very interesting field in the near future to adapt this innovation. Allison et al. (2007) stated that the gamer is listed as the first BCI user, given that BCIs give a useful and reliable feature. Van Erp et al. (2012) have also predicted that games and entertainment will be the first mainstream use for unmedical BCIs. The fBNCI project reported that BCI is the second of the top five most successful BCI support software frameworks (Future BNCI 2014). The number of potential users of BCI applications is largest (Ahn et al. 2014), and the financial viability of BCI technologies is high too (Van Erp et al. 2012). Furthermore, appropriate BCI devices with sensors that do not need gel are launched on the market (Ahn et al. 2014). Taking into account these advantages perceptions of BCI-based games and the production for the public of EEG instruments, it does seem apparent that the first successful use of the platform would soon be BCI-based games, whereas BCI's medical technology is often presented as a groundbreaking technological software.

This means that playing instructions should be operated at the exact real time with less delay and never changing user state. The BCI EPOC device should be calibrated to control the game in a proper way. Moreover, there are not many games designed and developed to be used with a BCI device. A BCI game needs to be designed and developed in an accurate way to utilize BCI device capabilities completely.

Related Work

Virtual technologies can be strong BCI advocates and video games. Researchers showed that BCIs provide the correct interface instruments for both video games (Ismahafezi et al. 2018) and VR (Abuhashish et al. 2015a; Abuhashish 2020) applications. On the other side, the researchers widely agreed that VR is a promising and productive platform to create more research and improve BCI systems. The process of interaction with the virtual environment can be subdivided into specific tasks (Wang et al. 2011), for instance, to select and manipulate or change viewport of any objects in the virtual environment.

The latest BCI technologies in the virtual world will allow users to modify the position of camera within a video on the left or the right using two different brain stimuli, including left- and right-hand motor imagery (MI), or two visual-evoked lasting potentials (SSVEPs). Also, MI-based BCIs were useful for controlling the

direction of a virtual car (Wang et al. 2011), navigating a virtual bar (Ismahafezi et al. 2018) or moving along a virtual environment or via a virtual plane (Abuhashish et al. 2015a; Abuhashish 2020).

Many medical and research games were designed to study the effectiveness of brain-controlled interfaces. At The University College Dublin and MediaLabEurope, the researchers developed a BCI-based video game called MindBalance (Wang et al. 2011) for engaging with virtual environments. In response to phase-reversing checkerboard patterns, the formed BCI uses the SSVEP created. This SSVEP significantly simplifies the techniques of signal processing so that clients have little or no instruction (Yisi Liu et al. 2010; Wang et al. 2011).

Neurofeedback studies have been carried out based on existing video games with different game consoles, such as Nintendo and PlayStation (e.g., Spyro the Dragon). In second life (Pineda 2003), and the MindBalance simulation (Lalor et al. 2005), movement visualization-testing techniques have been used. In Second Life, First-Person Shooter game (Pineda 2003), MindBalance game (Lalor et al. 2005), and Pacman (Wang et al. 2011), the researchers used motor imagery applications. Low-cost EEG-developers have created neurofeedback's-modulated, exciting, and difficult games (e.g., Neurosky, Nintendo, Microsoft, and Arena by Emotiv) that are frequent-play-motivating for the user.

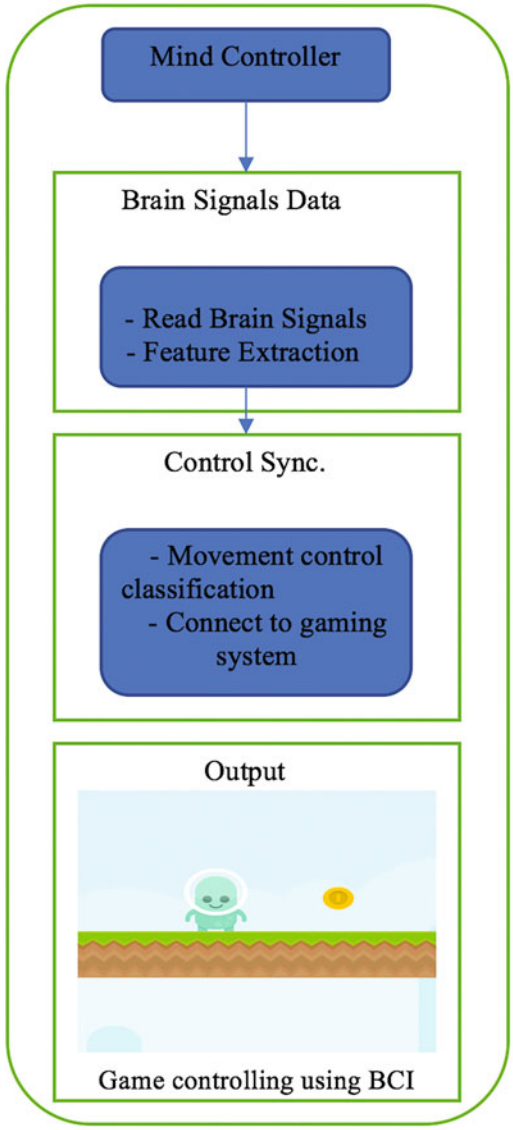
With regard to the literature study (Abuhashish et al. 2015b), it is believed that the developed EEG-based ADAPTIVE Game will sustain the user involved in the game as the complexity level is changed by cognitive assessments of the participant. The results of the BCI proved high in avoiding disruptive visual stimulation and were relatively consistent over six topics in the visually rich environment of the match, with 41 of 48 players being successfully achieved. Eighty-nine percent of respondents had acceptable precision in real time. Many subjects also increased progress in the completion of the game. It indicates that a more focused attitude and experience to the fixation of information contributes to a better visual reaction.

Problem Statement

The approach of controlling games using BCI has been eagerly awaited by game players since the game players did not feel that they reflect the reality of their situation while playing games using the traditional way. Furthermore, occasionally, some issues like slow response time in traditional game controllers appear, thus causing disappointment. In addition, spending a long period playing with traditional game controllers causes issues regarding health. It was believed that using a brain-computer interface as a new game controller may solve the issues as mentioned earlier. Although this research area appeared relatively recently, it can grant us a glimpse of the evolution of game controllers in the future. Nevertheless, the existing BCI technology like EPOC device does not focus on the game controller's application. Furthermore, until today, there are not many games that are designed using BCI technology. For the mentioned reasons, BCI-based games need to be designed to make the best use of brain computer-interface technology by providing a better level of immersion to look and feel real. Many approaches are used in the five main phases that are stated in Fig. 1.

Significance of the Study

Virtual reality has been utilized in several areas including gaming (Abuhashish et al. 2015a). In all previous studies, the main focus was on the world of virtual reality in many fields. Moreover, controlling a game using users' brain signals has a strong effect on enhancing the interactivity due to the expanding range of utilizing brain signals to control the virtual environment, which still needs more definition with efforts. Therefore, this scenario depicts a significant research area to be investigated. The proposed approach attempts to



Gaming Control Using BCI, Fig. 1 Used approach

combine users' brains with the gaming system using BCI (Abuhashish et al. 2015b).

Brain Signal Classification

In order to produce an accurate classified controlling system to be ready for mapping and synchronizing with the gaming system, the acquired mental activity obtained by brain signals must be subjected to preprocess by means of features recognition. Therefore, there are lots of BCI-based controlling recognition methods that have been proposed and implemented within the last few years. All of these works involved the extraction of electroencephalogram (EEG) signals from brain activities (Fig. 2). Then, the signals are classified into several parameters suitable for controlling the game accurately.

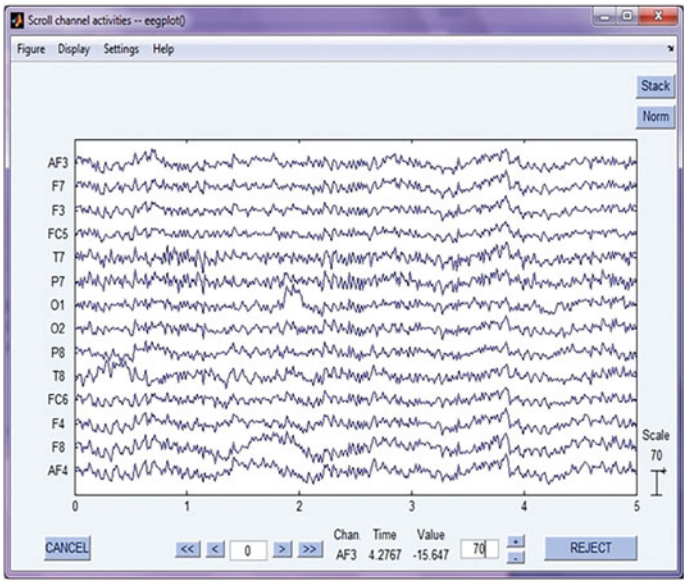
HIGUCHI Feature Extraction

In 2010 and 2011, Yisi Liu et al. (2010) and Wang et al. (2011) introduced fractal dimension FD based on the algorithm of quantification of primary controllers and described its implementation as feedback in virtual environments. Players' controller is recognized and visualized in real time on their virtual game by adding a parameter called "controlling dimension" to human-computer interfaces.

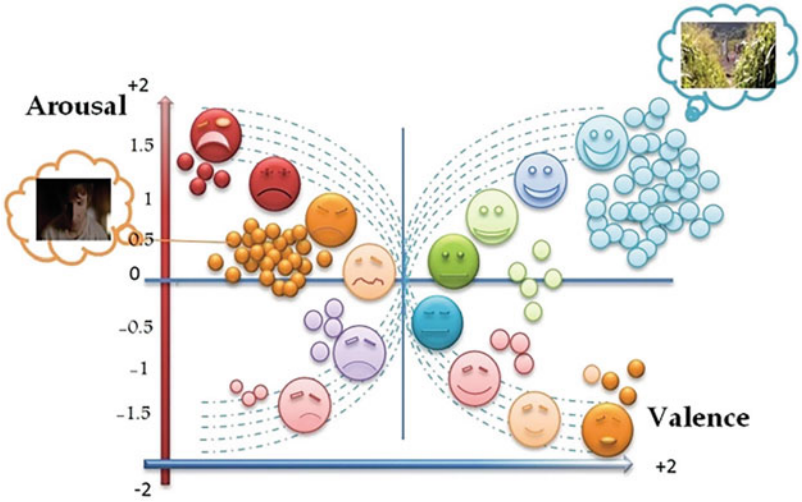
In this study, Higuchi algorithm (Higuchi 1988), based on fractal dimension computation values, was used. Higuchi algorithm provided improved accuracy, unlike other fractal dimension algorithms as stated in the study of (Russell 1980; Yisi Liu et al. 2010). At this point, the Higuchi algorithm was evaluated using Brownian and Weierstrass functions, where theoretical FD values are known.

To summarize, when comparing the HIGUCHI fractal dimension calculated values with the Mean, they are identified as a form of control state by correlating them with the representation of control in the arousal-valence model. Any change in the result of HIGUCHI fractal dimension is mapped alongside the axis of arousal (Fig. 3), where the high value of HIGUCHI fractal dimension result is positively related to high arousal level.

The Higuchi algorithm determines the fractal dimension (FD) quality of regression details. Wang et al. (2011) say that the Higuchi algorithm (Higuchi 1988) can be relied on in order to calculate high accuracy in contrast to other fractal dimensional algorithms. A research assessment on Brownian and Weiestrass methods (Wang et al. 2011) has verified the utility of Higuchi algorithm. However, the high value of the findings of Higuchi Fractal Dimension (HFD) is likely to generate an improved anticipation. Eqs. 1 and



Gaming Control Using BCI, Fig. 2 Controlling brain signals



Gaming Control Using BCI, Fig. 3 Valence_arousal model for movement control recognition

2 have illustrated the main parameters used as the main parameters in HFD algorithm.

Given a time series of one dimension *x(1),x(2),* ⋯*,x(n)s,* the HFD calculation algorithm can be defined as below:

Step 1: *Select one value of k*

Step 2: *Construct the subseries* $X^m{}_k$ *from the time series as following*

$$X^m{}_k = x(m), x(m+k), \cdots, x(m+[(n-m)/k] \times k) \quad (1)$$

where $m = 1,2,\cdots,k$ and [ ] denotes Gaussian notation that rounds a number in the square brackets to its maximum integer equal to or less than themselves, m the initial time, and k the time interval. For example, when $k = 3$ and $n = 100$ having three subseries as follows:

$$X^1{}_3 : x(1), x(4), x(7), \cdots, x(100)$$

$$X^2{}_3 : x(2), x(5), x(8), \cdots, x(98)$$

$$X^3{}_3 : x(3), x(6), x(9), \cdots, x(99)$$

Then each subseries length $X^m{}_k$ is calculated. Length $L_m\,(k)$ of $X^m{}_k$ is equal to

$$\frac{\left\{\left(\sum_{i=1}^{int\left(\frac{N-m}{k}\right)} |x[m+ik] - x[m+(i-1)\times k]|\right)[(N-1) \div (int((N-m) \div k) \times k)]\right\}}{k} \tag{2}$$

Step 3: *Calculate the average length L(k) of all Lm(k)*

Step 4: *Repeat step 1–3 for several values of k*

Step 5: *Slope of the curve of ln(L(k))* versus *ln(k) is approximated. FD value is the slope multiplied by −1.*

In a previous study of the algorithm Higuchi, this algorithm demands that the principal EEG signal be divided into many signals to boost the readings of human motor imagery and to create new parameters. This improved outcome results in higher reliability and allows further motor imagery to be explored. For these purposes, the fractal dimension of Higuchi is ideal for most human motor imagery.

Control Classification Based on the Circumplex Model

It has been considered that each controller relates to an approximation interval within the arousal-valence model based on the Circumplex model (Davidson et al. 1990) as in Fig. 4. To analyze the EEG signals in terms of mind controller, two frequency bands are usually considered: alpha (8–13 Hz) and beta (13–30 Hz). It has been shown that the power of these sub-bands carries useful information related to controller states. In 1988, Higuchi (1988) showed that the left hemisphere controls the right movement, which causes a minimal amount of alpha-band power, whereas the right hemisphere causes minimal alpha power and, in turn, controls the left movement. Moreover, Higuchi (1988) found that the peak in the frequencies of alpha-band power increases when the human is subjected to movement control order.

Control Dataset

Since the recognition of control movements is about a new domain, a dataset of EEG signals benchmark needs to be set up that could be used for further EEG-based control recognition studies. In this study, by depending on the emotive brain controller device, the dataset was collected after applying a specific stimulus scenario in the course of analyzed movement control to come across the inner movement control imaginary patterns (Fig. 4).

Gaming Control Using BCI, Fig. 4 Collecting movement imaginary brain EEG data signals

In addition, the research strongly depended on building questionnaires that can furnish us with the right subject regarding stimuli. In the subject matter, an individually random person was examined by giving certain stimuli to acquire imaginary movement control such as go forward, go left, go right, and jump.

Control Mapping

After the classification process, the real human imaginary movement control to the Circumplex model was mapped. This process involved all real imaginary movement control that represents all categories of the control stage.

Game Animation

External effects and user interaction control the game. Controlling a game based on movement control imaginary is considered one of the promising research domains in the animation field (Abuhashish et al. 2015b) since there is a lack of interaction between game players and games in the course of mind controller (Abuhashish et al. 2015b; Ismahafezi et al. 2018).

Some ideas and concepts have been explored and applied to bring more significant game controllers and devices in the last few years (Wang et al. 2011). Furthermore, in the majority of prior research, a wide range of devices has been employed to create immersive games and virtual reality experiences associated with control systems, aiming to achieve high levels of quality. The devices mentioned in the introduction are considered popular even without players and do not reflect user sentiments.

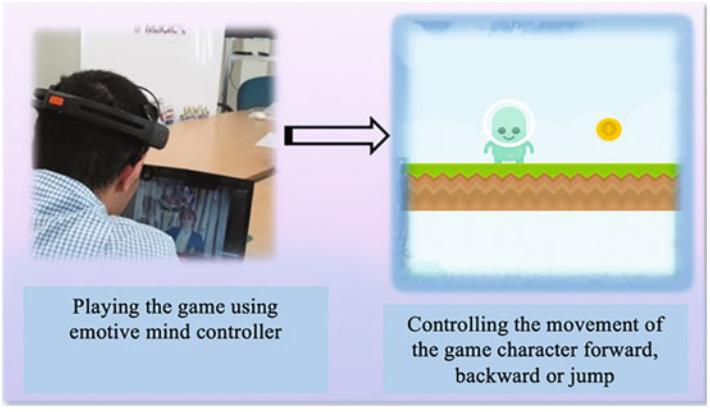
Game Controller

Real human control generated from mental activities means that the main controller of any human movement is the human mind based on certain reactions. In this study, the focus was given on human movement control stimulated by their reactions. Each movement control has an approximation degree of angle that represents the changing direction of the controlling process that expresses the imaginary movement control such as go forward, go left, go right, and jump (Fig. 5).

Behavior Controlling

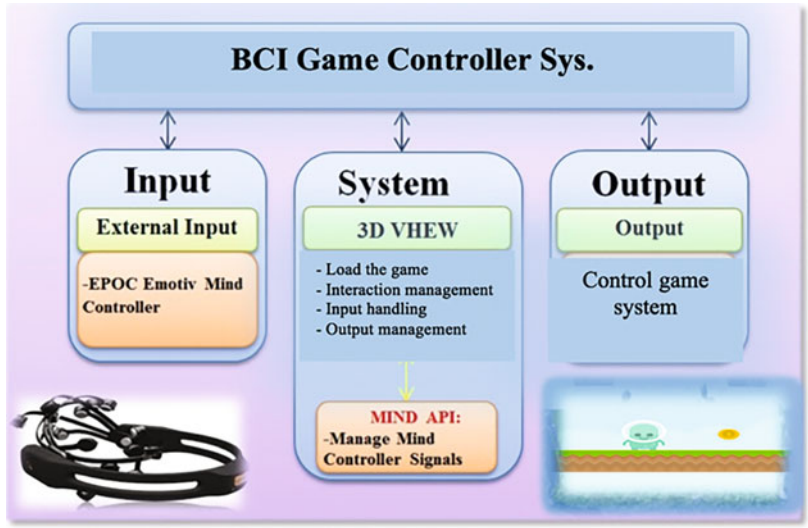
Mental role control works by its action/reaction. Real human behavior and characteristics simulation in the gaming system has been growing in the field of computer graphics and multimedia. However, there are many scientific studies regarding real human behavior and characteristics that involve their recognition with their application (Ismahafezi et al. 2018).

Based on previous methods, this research come up with parameters to control the action/reaction of the gaming system in terms of imaginary movement control in which each is represented by a particular parameter to come up with its related behavior. By using the mind controller, the mental activities can be sync and control. In this study, one of the famous low-cost devices for the mind



Playing the game using emotive mind controller
Controlling the movement of the game character forward, backward or jump

Gaming Control Using BCI, Fig. 5 Go forward transition



Gaming Control Using BCI, Fig. 6 Operational framework for game control using BCI

controller, namely, emotive, was used, which consists of several sensors.

In this proposed framework (Fig. 6), the walking movement was represented based on game players' action/reaction. For instance, if the player wants to move forward, his imaginary movement will be mapped based on the mapping method and will be synchronized with the gaming system.

Conclusion

The utilization of the brain interface can provide strong credibility and impression to the users in any field. In this entry, an innovative framework has been studied to show how to synchronize and control the gaming system based on imaginary movement recognition from EEG signals using BCI. Higuchi FD algorithm with a gaming system was implemented since it can provide real-time analysis and sufficient accuracy. The study reveals that BCI can be used in many fields, including augmented reality, virtual reality, virtual environments, and games.

Synonyms

Casual game; Mobile game; Puzzle game

Definitions

Casual game:	A game that is designed to be played occasionally for a relatively short period of time without losing points or competitive advantages.
Puzzle game:	A game that requires solving puzzles in order to advance in the game.
Mobile game:	A game that runs on mobile phones.

Introduction

Gardenscapes: New Acres and Homescapes are puzzle matching mobile games created by Playrix. Gardenscapes came out in 2016, and Homescapes was released a year later in 2017. They became extremely popular with over 1 billion downloads (Chapple 2020). Being casual games, they both require very little skill and are easily accessible on smartphones as well as Facebook.

Gameplay

The main story in Gardenscapes and Homescapes follows Austin the butler as he is renovating either his family garden in Gardenscapes or his family mansion in Homescapes. The player names themselves and picks an icon to represent themselves in the game. By completing various side challenges, they can unlock new icons to represent their new achievements. The player also receives new icons by completing renovations in specific areas. These icons can be customized to best fit each player. By solving puzzles, players earn stars that can be used to clean and renovate the property as well as to unlock new areas. Each puzzle board has a goal that can be completed by matching three collected pieces or removing bubbles/bushes.

Figure 1 shows a puzzle board which is the main form of gameplay in both Gardenscapes and Homescapes. This specific puzzle board has cookies which can be broken by making matches next to them. The side panel shows that there are 15 moves, meaning that a player must collect the required items in 15 moves or less. It also shows what is required for this puzzle board: donuts and boosters. For example, the player must make the donuts drop to the bottom of the board. Players can use boosters bought before the board starts to assist them in puzzle solving.

Although the specific mechanics and objectives of Gardenscapes may vary across different versions, here is the basic gameplay loop in Gardenscapes:

1. Match three or more same objects to clear them and earn points.

Gardenscapes and Homescapes, Casual Mobile Games, Fig. 1 A puzzle board in Homescapes

2. Complete tasks assigned by the characters to progress in the game and earn points.
3. Use points to buy and place items in the garden to decorate it.
4. Discover hidden secrets and interact with characters to expand the garden further.
5. Repeat the process to complete the game and restore the garden to its former glory.

Similarly, Homescapes offers varying mechanics and objectives in different versions, but here is the gameplay loop in Homescapes:

1. Match three or more same objects to clear them and earn points.
2. Complete tasks assigned by the characters to progress in the game and earn points.
3. Use points to buy and place items in the house to decorate it.
4. Discover hidden secrets and interact with characters to expand the house.
5. Repeat the process to complete the game and renovate the house to your desired design.

Since the puzzle games are mostly luck based, there is very little skill required to win the games; it is out of the player's control where the extra pieces fall. Players have to think on the fly and adapt quickly to sudden changes. With that being said, the longer a player plays the game the better they will get at recognizing moves that will increase their chances of winning. By teaming up with friends and other players, they can help each other out by tips for the levels or gifting each other extra lives.

In-App Purchases

Although there are in-game coins that give players additional moves or lives, the games offer both free and payable prizes. For this specific microtransaction, players can pay $4.99 for a golden ticket to unlock many rewards that the player can obtain by playing the game and collecting specific pieces for that golden ticket event. There are other microtransactions such as spending real money to buy in-game coins that can be used to give a player additional moves as well as additional lives.

Reception

While the games had seen much popularity with a large number of downloads, they ended up getting a rather negative reception when they created ads that did not truly represent what the games were about. The advertisements for the two games would show game footage that was nothing like the actual gameplay. Many players first downloaded the games expecting a very different experience than what the games provided. There had been talk of banning the ads as many people accused the game publisher of false advertising (BBC 2020).

Conclusion

Mobile games are a great way for anyone to get into playing video games. Gardenscapes and Homescapes are examples of easy-to-play casual games because they are easy to get into and they require little to no skill to play. Gardenscapes and Homescapes' main gameplay loop appeals toward casual gamers (Hörgstetter 2020). With each level, a player earns stars that can be used to renovate different areas. Players feel rewarded by completing levels as well as being able to complete renovations on a mansion or garden.

Artificial intelligence; *GA* genetic algorithm; *NPC* non-playable characters; RPG role-playing game

Definition

Using genetic algorithm for creating non-playable characters is the process of creating similar-looking characters from a wide variety of parent characters. After the production of subsequent populations, the characters that exhibit the best traits are chosen as the final selection.

Introduction

Non-playable characters have always been a special part of video games. Their appearance is more pronounced in role-playing games like the Elder Scrolls® series and the Fallout® series or in the open-world games like the Grand Theft Auto® series or the Assassins Creed® series. The presence of these characters is either to provide the player with objectives to complete or give a sense of a living world with people going on about their business. The variety of these characters is however lacking which takes the player away from the illusion of a believable world. This lack of variety is attributed to the amount of man-hours required to craft an individual character. With a tight budget, the number of these individuals remains

small; hence, the same characters are repeated throughout the game.

In this article, the utility of using genetic algorithm for creating non-playable characters in games will be discussed. The previous approaches regarding the use of genetic algorithm for creating characters will be explained first, and then the usage of this algorithm in modern games will be analyzed. Finally the advantages of this technique will be explained as opposed to the normally used method of character creation.

Usage of GA

GA has been used in many research applications and character creation has not been any different. Improving AI has been a major concern as GA was used to improve the bot behavior in Unreal Tournament 2004 (Bullen and Katchabaw 2008). It has also been used to design decision trees to be used as bot's AI in the game Planet Wars (Fernández-Ares et al.).

GA has been used for defining the mental attributes of an NPC (Khan and Okada 2013). The mental attributes of characters were composed of actions which were distributed into good and bad actions. The good actions were allotted low numerical values, while the bad actions were given high numerical values. The concept here was that if the sum of the actions was small, then the character's mental attributes contained mostly good attributes. If the sum of the actions was large, then the character mostly contained bad actions. By desiring a certain sum by the administrator, the GA tried to fit the actions such that their sum came close to the required value thus ensuring that an appropriate character is selected with a random combination of actions.

Other uses have been to create creatures which move and behave in a simulated 3D world. The morphologies of creatures and the neural systems for controlling their muscle forces were both generated automatically using genetic algorithms (Sims 1994). Genetic algorithm has been used for breeding of multiple selected parents to produce offspring via crossover and mutation functions and also for using a single parent to generate variations of a creature through mutation (Hudson 2013).

The usage of GA has been prevalent in various areas of character development from improving the AI, creating the morphology of the character from scratch to creating new breed of similar-looking creatures by using already defined parents through mutation and crossover. Video games have however not made use of this algorithm for defining the NPCs due to several reasons. One of the main reasons has been the amount of characters that can be viewed on screen at a time. Games are always trying different tips and tricks to give an illusion of huge crowds with the least amount of processing power and memory usage. The most common methodology for showing a large collection of NPCs is to use sprites as shown in Fig. 1 where several sprites are repeated to give an illusion of a large collection of people.

This technique is commonly used in modern games where the NPCs only behave as bystanders and do not play an active role in the gameplay. These can be treated as graphical artifacts used to enhance the immersion of the player when the focus is more toward the other features of the game than the player-NPC interaction. In older games like Doom®, which was a First-Person Shooter game, all the enemies were also made up of sprites as it helped to generate a large quantity of NPCs on screen even with low processing power as shown in Fig. 2.

The problem with sprites, however, is that, if we want to have variety, we will need to generate art for every individual character which will increase the art assets, causing a huge demand on memory to store those assets, thus degrading performance. As a result, the NPCs are identical copies of each other and do not exhibit randomness in appearance.

With the shift in displaying a character in 3D rather than in 2D, the possibility of defining randomly generated characters has been made possible. With games like Assassin's Creed Unity®, the current hardware is able to produce about 30,000 characters on screen if required as shown in Fig. 3.

Genetic Algorithm (GA)-Based NPC Making, Fig. 1 Crowd made up of sprites in Forza Motorsport 5®

Genetic Algorithm (GA)-Based NPC Making, Fig. 2 Multiple sprites on screen in Doom® (n.d.)

With that many characters on screen, a method is required that can cause the characters to adhere to a certain criteria and yet appear randomly. At the same time if a persistent simulation is needed, where new characters are introduced to replace the old ones, the new characters should appear similar to their older counterparts by acquiring their various traits. Something similar was achieved on a very minor scale in the game Fallout 3® where the father of the character played by the user resembled the character in facial appearance and color. If GA is used for creating NPCs, it is possible to create a vast number of random characters which adhere to a certain criteria and can even be used to make the characters appear like people in a certain demographic. This will help in personalizing the game to the people playing in that part of the world.

Genetic Algorithm (GA)-Based NPC Making, Fig. 3 Thousands of NPCs in Assassin's Creed Unity® (n.d.)

Physical Appearance

Current games, especially RPGs, provide a host of features in order to let the players create a character according to their liking. Players spend countless hours just creating their own character using the tools provided before they even start to play the actual game. Elder Scrolls V: Skyrim is one such game where the player can define his own character with a plethora of options available. An example of the different types of characters that can be created is best shown in Fig. 4.

The character creation tools are normally very intuitive and can be used to create a vast majority of characters, but creating such characters takes time, and if we want to localize the look of characters according to a certain demographic, the task becomes overly complicated. An automated system in such a scenario can play a very good role in quickly producing characters, and this is where the usage of GA can be most beneficial.

There are two ways by which a character's 3D model can be created, the first being modular character while the second being mesh deformation. Both techniques have their advantages and disadvantages. In a modular character, each individual part of the body is modeled separately. There is a skeleton of every character which keeps these modules in place. The modules are swapped to produce a random-looking character which means that every module should have a wide variety of types to choose from (Khan and Okada 2013). The disadvantage of this technique is the need to create 3D models of each body part, and this number can increase exponentially depending on how fragmented the character model is desired. The advantage however is in defining various clothing articles that can be put on the character to make it appear different.

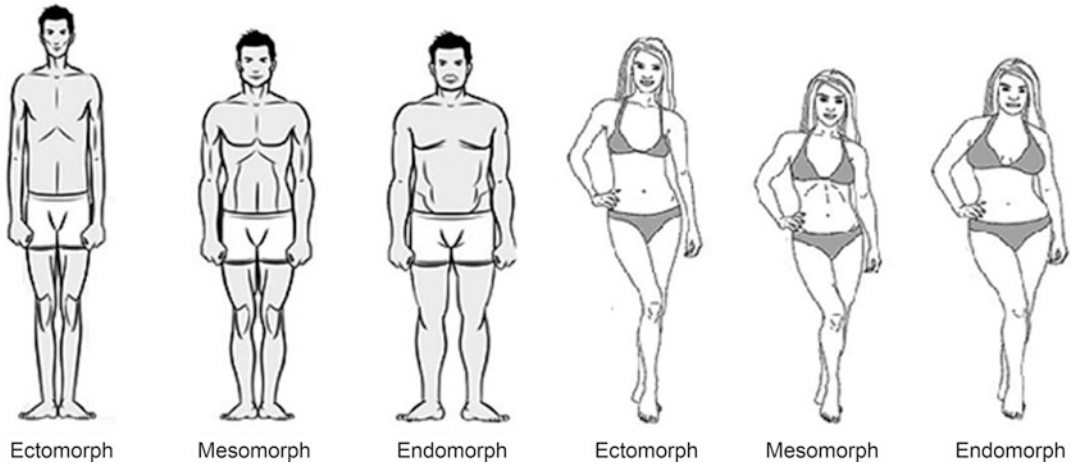
Mesh deformation allows a single mesh to be changed by changing different numerical values. This means that the amount of effort required to make a 3D mesh is quite minimal. However careful calculations and algorithms need to be developed so that the created mesh looks realistic and allows changes within the believable body shape and size. It also requires that the users are provided with some predefined settings as a starting point for their character generation and they build upon that while defining their own characters.

Genetic Algorithm (GA)-Based NPC Making, Fig. 4 The many character options in Elder Scrolls V: Skyrim® (n.d.)

Elitism and Sigma Scaling

The problem with NPC creation with GA is two-fold. We want to create characters that first adhere to a certain set of values over a wide range of values. We then also want the characters to exhibit randomness within those characters so that they fit the selection criteria and yet remain different from each other. One way to solve these issues is to use elitism with sigma scaling. Elitism ensures that the best individuals within a population are retained and they are used to perform crossover and mutation with other members of the population to create new individuals. The benefit of this approach is that the algorithm converges to a solution quickly. The disadvantage of this approach is that the algorithm might get stuck in local maxima/minima from the beginning and might not find out the best solution. The disadvantage however favors its use because an ideal solution is not a requirement for NPC creation. There needs to be a certain degree of randomness which elitism will provide in this case.

Sigma scaling will however ensure that the baseline of the fitness values remains near the



Genetic Algorithm (GA)-Based NPC Making, Fig. 5 Different body types (n.d.)

average (Hancock and Fogarty 1994). Standard deviation ensures that only those values are selected that are closer to the mean. It also requires that there is some order in values that represent the different mesh shapes or modules when defining a character. This is necessary as in real life similar-looking people live in different areas around the world. The differences in height, color, and shape of people vary a little within a local community, but it starts to vary as you move further away. As a result, parent characters that represent a community will need to be defined, and their subsequent generations will produce characters which are random and yet adhere to a defined criterion.

From a fitness point of view, a human body has three body types, namely, ectomorph, mesomorph, and endomorph as shown in Fig. 5. We can clearly see the body structure between the three types which means that their body shape attributes will be quite different from each other. These attributes do not take into account the facial structure and skin color which will also increase the number of attributes required to define a character physically.

As a result, the fitness values for the characters belonging to different demographics are going to be different. GA can use these values to approximate the desired character as requested by the users. This can even play a major role in approximating the child populations based on the interactions between the parent populations. If there is a persistent simulation, it will mean that characters belonging to different demographics are going to breed together through migration which is normally a function used in distributed genetic algorithm implementation.

Conclusion and Discussion

Genetic algorithm has been used in creating characters in unique ways from defining the mental attributes of a character to physical definition. GA works by mimicking the nature's way of natural selection to find the best possible solution to a problem. The usage so far has been to optimizing the AI, for deciding the mental attributes of characters in an RPG setting, for defining the physical appearance of the characters, and for creating optimized morphologies of creatures to improve their movement in a 3D space. By combining these researches together, it can be hoped that GA will be quite useful in the creation and optimization of NPCs in games and also in creating lifelike simulations where characters will improve with time and we are able to see the changes in the population due to breeding, crossover, and mutation and how it affects the overall environment created within a game.

Single-player game; Action adventure game

Definitions

Single-Player Game = a game that is designed for single-player mode where only one player is expected throughout the entire gameplay

Action Adventure Game = a game that combines core elements from both action game and adventure game genres

Introduction

God of War is an action-adventure game franchise developed by Santa Monica Studios and published by Sony Interactive Entertainment that owns the game studios. This article is about the 2018 God of War in the franchise that was released for PlayStation on April 20th, 2018 (Goldfarb 2018). Following the life of Kratos and how he went from being just a demigod, the son of Zeus, to the god of war in Norse mythology. It is a solo, story-focused game that follows a father and his son on a journey across the nine realms.

Gameplay and Story

God of War (2018) is a single-player third-person action adventure game. A god named Kratos and his son Atreus embark on a mission to spread Kratos' wife's (Atreus' mother's) ashes on the highest peak of all the nine realms of Norse Mythology. Kratos must come to terms with the loss of his wife while also learn how to transition from the finely tuned instrument of war he once was to a caring father for his son. Kratos struggles in deciding whether or not to tell Atreus of Kratos' goodlihood and what that means for Atreus. Eventually, Kratos will be forced to make this difficult decision if he wants to mend Atreus and make him whole.

The game consists mainly of dialogue, actions (fighting), and puzzles. The main weapons in the game consist of Kratos' Leviathan Axe—an axe from Norse mythology that is primarily a cold or ice weapon, and Kratos' Blades of Chaos—twin Greek blades both linked to chains connecting to both of Kratos' arms as a fire weapon. Both the ice and fire weapons are essential for some of the puzzles as well as the fighting because enemies often have a certain damage type: they are either resistant or not. Kratos also has a guardian shield given to him by his wife before her passing. The shield can be used for both offense and defense. Finally, Atreus wields a Talon Bow that can shoot regular arrows, light elemental arrows, or electric elemental arrows. This weapon is important for both combat and puzzle solving.

Gameplay Mechanics

God of War (2018) introduces many new mechanics including new combat mechanics, puzzles, and a system for equipping gear, equipping abilities, and upgrading the gear and abilities (Hornshaw 2021). The combat mechanics involve Kratos using his axe, blades, and shield to fight various enemies. Combat also involves Kratos commanding Atreus to fire his bow at enemies using specialized ammo. The types of weapons the player uses mostly depends on the player's preference as well as the types of enemies. For example, some enemies are immune to Kratos' axe because it is an icy weapon, so the player must switch to either the shield or the blades to defeat the enemy. If an

enemy is immune to the axe, it will usually be more effective to use the blades to defeat the enemy since the blades have the fire damage type.

Unlike previous games in the God of War franchise, Kratos has an armor that can be collected, crafted, and upgraded. These upgrades allow the player to increase Kratos' stats and make him more effective in combat. The upgrades can also be used on Kratos' main weapons to make them stronger while also changing their appearance as player upgrades the weapons. In addition to selecting the type of armor Kratos wears, higher-quality armor pieces provide additional bonuses for the player to exploit. The type of armor the player equips also influences six stats that apply to Kratos. Kratos' stats are strength (damage from standard attacks), runic (elemental and special attacks), defense (reduces damage taken), vitality (increases maximum health), luck (increases chance perks, experience, and money), and cooldown (reduces recharge time of special attacks).

The player also has access to several abilities that may be used along with the weapons. Kratos' axe and blades both can be equipped with up to two abilities each that can be described as a "special move." These abilities can be used as a powerful attack that has a much more significant cooldown than Kratos' basic attacks. In addition to these abilities, Kratos can also have another ability not linked to his weapons but can provide a buff to Kratos. For example, one of these abilities resets the cooldowns of all his other abilities. The player can also give Atreus an ability to use as well where Atreus will summon an elemental animal or animals to attack enemies. The type of animal and the number of animals depend on the ability selected for Atreus (IGN 2018).

Playable Characters

The only playable character in this game is Kratos. Kratos is a former demigod/spartan warrior who eventually became a god by killing the former Greek god of war, Ares. While Kratos is the only character the player can directly control (such as movement, attacks, combos, etc.), Atreus can be indirectly controlled by the player. Kratos wields two main weapons, the Leviathan Axe and the Blades of Chaos. Atreus utilizes a bow. The player is not able to force Atreus to move to certain places, but the player can make Atreus fire an arrow at a target or an area by looking at the target or area and pressing the button or key corresponding with Atreus' shoot action. Atreus will then fire an arrow at the target.

Reception

God of War (2018) has sold about 19.5 million copies as of August 2021. This figure comes from sales for PlayStation consoles alone, as this was before the game was released for PC (Stockdale 2021).

Conclusion

The main enjoyment players receive from God of War is the amazing and thrilling story, combat and leveling systems, the mythology lessons, and the experience of conversing and/or fighting the many Norse mythological creatures and gods (Moore 2022). This title is particularly appealing to those who enjoy a good story and mythology.

Synonyms

Hack-and-Slash; Action-Adventure

Definition

Hack-and-Slash = a subgenre of action games that challenges the player to fight hordes of enemies that seem weak individually compared to the powerful player character. They typically ask a player to complete a level filled with minor enemies with a more powerful enemy at the end.

Action-Adventure = A mix of the action and adventure genres. Action-adventure games typically have some fast-paced fighting elements of action games with a story and world of an adventure game.

God of War, a single player game created by Santa Monica Studios on the Bluepoint Engine, was published and released by Sony Computer Entertainment on March 25, 2005. The game is part of an eight-game series spanning across multiple Sony consoles. As of August 2021, *God of War 4* has sold over 19.5 million copies, making it the best-selling PlayStation 4 game as well as the best-selling game in the series.

Throughout the entire series, *God of War* has always been called a Hack-and-Slash or Action-Adventure title due to its extremely gory battles and in-depth storytelling. As a result, the game carries an M for mature rating for every title.

The game begins with no real explanation or character introduction. The main character Kratos simply says, "The Gods of Olympus have abandoned me," and he stepped off the edge of a cliff to lead the player into thinking that Kratos has fallen. The entire storyline for the first game is based around Kratos trying to vanquish the God of War, Ares. Throughout the game, the player controls Kratos and gathers many weapons and magical items and spells for use in their quests. The monsters consist of the undead and other ancient Greek creatures, living, undead, or holy. Due to the naturally bloody storyline and combat features, the target audience for this game are teenagers and adults.

Gameplay can be controversial as there are some players who find that dealing with the same combat mechanic repeatedly can be quite boring, but others think that the new stream of weapons that can be collected keeps things interesting. The mechanics include a simple series of light and heavy attacks, including specialized finishers that are completely different for every enemy the players face. The developers also threw in other special attacks that are unlocked as players progress through the story, such as different magic attacks. Other than these few simple gameplay mechanics, there is not much that *God of War* brings to the table.

Other than the latest installment in the series that takes place in Nordic history, all the previous installments take place in Ancient Greece. The story revolves around the death of Kratos' family, who were killed by Kratos himself under the influence of Ares. Kratos swears revenge for his fallen loved ones and sets out to find the ancient Greek artifact called Pandora's Box. Legend says that this box, when opened, could give any mere mortal the power to kill a god. Kratos plans to use this box to slay Ares for vengeance. Throughout this journey, players meet actual Greek mythological characters, such as Athena, otherwise known as the Goddess of Wisdom.

Levels in this game are not meant to be more than just a quick change of environments, but

rather a smooth flowing of events from one area to another in order to strengthen the effect of the storytelling. To give an example, after the players find out that they need to travel to the Desert of Lost Souls to retrieve Pandora's Box, they are met with a cutscene or backstory that explains why Kratos needs the box in the first place. This cutscene shows Kratos working for Ares by destroying villages who do not follow the ways of God. Only when it is too late does he realize that he is being manipulated by Ares into targeting the village in which his family resides. This cutscene gives the players the reasons for all these events in the game.

The entire game is played in a third-person mode with some cutscenes going into first-person mode. The interface consists of a health and mana bar at the top left corner. Instead of an enemy health bar, players get a finisher button for when an enemy is weak enough to be killed. If there is a boss in the vicinity, a new bar that contains the boss' or bosses' health will appear down at the bottom of the screen that is both larger and longer than the health bar.

God of War was one of the major titles in the Playstation 2's game lineup, and it is conceived as one of the most popular Playstation 2 games, selling 4.6 million copies. Its success has led to seven sequels (Harradence 2019).

However, *God of War* has one major controversy on the subject of nudity in the game (Cooper 2017). While most players thought the mature rating was due to the blood, gore, and violence, some of the player base was met with a surprise when they are given the opportunity to interact with a woman on bed. Although players do not see anything obscene, they can certainly tell what is happening from the sounds and right joystick movements. There are also creatures in the game who lack clothing, and the player is forced to see them naked when fighting them, thus unnerving some players who do not want or intend to see this.

Looking at the *God of War* series, every game in the series so far has received good reviews from GameInformer, IGN, and others. In fact, the latest installment got a perfect 10/10 rating from IGN. For the very first installment, many people opined

God of War, an Analysis, Fig. 1 God of War 1

that *God of War* was the highlight of Playstation 2. Alex Navarro of GameSpot wrote, "*God of War* is one of the best action adventure games on the PlayStation 2, and it should not be missed" (Navarro 2005).

Here is a brief history of the *God of War* series:

The first *God of War* was released in March 2005. It has wonderful graphics for that era of gaming. The game is often called the highlight of Playstation 2's life and is generally highly

God of War, an Analysis, Fig. 2 God of War 2

God of War, an Analysis, Fig. 3 God of War 3

God of War, an Analysis, Fig. 4 God of War 4

recommended. The music consisted of loud choirs followed by other instruments, such as gongs, to give a sense that the main character is powerful (see Fig.1).

The rest of the games throughout the series all share the same concept, but the visuals and sounds have improved. New weapons and abilities were thrown in as the series progressed. The storyline has also changed throughout the series. Kratos goes from killing one god to killing all gods which throws the world into chaos. Here are a couple of images to show the boss fight progressions through the games (see Figs.2 and 3).

The real changes to the game occurred in *God of War* 4, with the introduction of a completely different soundtrack as well as a new style of combat and extremely detailed graphics. There is also a shift from Greek mythology to Norse mythology that introduces new gods, enemies, and landscapes. Krato's appearance was also changed in the new addition:

The following YouTube videos illustrate how music has changed from the earliest edition (God of War 1) to the new installment (see Fig. 4)

Anti-Social Behavior; Ganking; Griefers; Griefing; Harassment

Definitions

MMORPGs refer to massively multiplayer online role-playing games, in which many players play cooperatively or competitively within a persistent world. Griefing is generally defined as a type of online bullying within a gaming context and is quite common in MMORPGs. Griefing involves one player intentionally disrupting another player's game experience, through some form of harassment, as they enjoy doing so.

Introduction

Massively multiplayer online role-playing games (MMORPG) are a genre of game that is played online with hundreds to thousands of people playing simultaneously. Each player controls an avatar and can play cooperatively or competitively in the persistent virtual world (Achterbosch et al. 2008; Wolf 2012). In MMORPGs and other online virtual worlds, players may encounter what is known as griefing. This is when one player deliberately disrupts another player's game experience for their own personal enjoyment, with potential in-game gain (Bartle 2007; Foo 2008; Foo and Koivisto 2004). The following is an example scenario that outlines this phenomenon:

> You've had a hard day at work. As soon as you arrive home, you log into the latest MMORPG to relax and wind down for the day. Your in-game avatar is inexperienced, so you approach a virtual farmer and accept their seemingly simple quest that will increase your character's experience points, as well as reward you with a small amount of gold.
>
> You proceed through the forest towards the location of the computer-programmed werewolves that have been terrorizing the farm. Exiting into a clearing you spot the alpha werewolf and engage in combat. You are winning the battle as you outrank the werewolf in melee combat. Just as you are about to strike the finishing blow, out of nowhere a veteran real-life player appears behind you and stabs you in the back, killing you in a single hit. They proceed to finish off the werewolf and collect the winnings for themselves, although to them the loot was secondary to the satisfaction of killing another player and halting their progress.

This scenario illustrates how a highly experienced player may use unfair advantage of

outmatched character progression to surprise attack a wounded and inexperienced player. This type of griefing action is known as ganking, and players have acknowledged that it and many other types of griefing occur regularly in MMORPGs (Achterbosch 2015).

Defining Griefing and Griefers

Bartle (2007) defined a griefer as someone who deliberately did something for the pleasure in knowing it caused others pain. Foo and Koivisto (2004) described griefers as players that engage in play styles that specifically disrupt other players experiences, while Lin and Sun's (2005) definition was similar with the addition that they derive enjoyment from their behavior. Barnett and Coulson (2010) relate a griefer to a bully, stating that these players enjoy participating in anti-social behaviors that disrupt other players' enjoyment of the game.

It is apparent that researchers agree on the overall terminology of the words griefing and griefer, with the perception that three effects need to be present for a player to be considered a griefer:

1. The action is intentional.
2. The action disrupts another player's enjoyment.
3. The instigator gains pleasure from the action.

If these three are present, then the player that causes the action can be called a griefer. Sometimes, the griefer is looking for more than just pleasure and using griefing as an instrument to gain something valuable to them within the game.

Pervasive Griefing Actions

Different types of in-game actions can be attributed as griefing according to the definition above. Ganking, as described in the introduction is one type, and 78.6% of a representative sampled audience defined this action as griefing (Achterbosch et al. 2013), while 9.0% of all players that are subjected to griefing indicated ganking happened to them multiple times per day (Achterbosch 2015).

Verbal Harassment is where chat and voice communications are misused to offend, harass, insult, threaten, or humiliate another player. This was commonly (just over 80%) defined as griefing, and only 19.0% of players that are subjected to griefing had never been griefed in this method. However, the most pervasive type of griefing is spamming, which refers to intentionally filling chat channels repeatedly with messages of low relevance or that are against the game rules. Just over 20% of the sample audience in Achterbosch (2015) indicated this occurred multiple times a day. Other highly pervasive types include spawn camping, ninja looting, and kill stealing. In contrast, a deceptive griefing type known as scamming is not very widespread with 64% having never been exposed to it.

Motivations for Griefing

Achterbosch et al. (2017a) discovered that griefers are motivated by a few factors of potential gain. Pleasure is a common factor among all griefers as prior research suggested, but power, challenge, and/or control are also strong motivating factors for some griefers. For example, the player that retaliates against a griefer with some griefing of their own is challenging the griefer, and through defeating them, feels pleasure. The player that manipulates and deceives does so as they find it pleasurable to control situations and the potential lucrative gains of monetary value serve to enhance their power.

Griefing behaviors can stem directly from the "Online Disinhibition Effect," which refers to abandoning inhibitions and regular social norms when interacting with other people online due to the anonymity and invisibility available and lack of repercussion (Suler 2004). With anonymity, a player's propensity towards griefing increases (Chen et al. 2009). Griefing may be directed at players of either opposing *or* friendly

factions. It was documented that more griefing was directed towards players of the same team within a participant observation of griefing (Achterbosch et al. 2017b). The author joined groups with total strangers on multiple occasions, often known as a "pick-up-group" or PUG, in which many cases of griefing was witnessed. With no fear from team disruption to stealing items to verbal harassment.

Impact of Griefing

Griefing can hugely impact the players subjected to each action. A well-known case revolves around a perpetrator "Mr. Bungle" performing virtual rape. This griefer manipulated the game mechanics and program code to sexually assault multiple inhabitants in an online virtual world (Dibbell 1999). Many players were in shock and some admitted to shedding tears in real-life. In further studies, it has been documented that many different types of griefing affect individuals in vastly different ways and levels of intensity (Achterbosch 2015). For example, 20% of new players subjected to griefing admitted that they played less, 7.1% stopped playing for a time, and 5.1% quit playing the game never to return. Players subjected to scamming and ganking indicated similar (but slightly lower) results. All three of these types of griefing were rated as high to extreme in intensity by roughly one third of the players subjected to them. The impact here represents a growing concern for not only players but also developers looking to keep a strong player base.

Conclusion

With the success of the MMORPG genre, griefing has become an extremely pervasive problem with differing levels of intensity for each griefing incident, and it needs to be addressed. In this article, definitions for MMORPGs, griefing, and the instigators of griefing, called griefers, have been provided. In addition, this article discusses motivations for causing grief, pervasive griefing, the impact, and identifies with a few examples, different types of griefing and griefers.

Definitions

Hades is a rogue-like hack-n-slash dungeon-crawler game that was developed by *Supergiant Games*, an independent studio in San Francisco founded in 2009, and is best known for their critically acclaimed games *Bastion* (2011), *Transistor* (2014), and *Pyre* (2017).

Development

Hades was first launched as an Early Access game originally in December 2018, exclusively on the *Epic Games Store*, then on *Steam* in December 2019. In September 2020, the team completed their Early Access development and launched v1.0 of the game, additionally adding the game on the *Nintendo Switch* platform. This game was given a Teen rating by the ESRB. The game was designed as an Early Access from ground up. This allowed the community to play a creative and important part in aiding the developmental process of the game, from design, worldbuilding, and storytelling, and helped the game naturally evolve (Schodt 2020).

Storyline

Hades places the player in control of Zagreus, the son of the God of the Underworld, Hades, as he attempts to escape from the depths of the Underworld and reach Mount Olympus. With every attempt that Zagreus makes escaping from his father, the Olympians on the over world aid in his endeavor. There are 30 differently fully voiced

© Springer Nature Switzerland AG 2024
N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

characters, allowing players to experience the story through thousands of unique events and interactions. The narrative slowly unfolds over the progression of the game, creating different opportunities and dialogue, about ten hours' worth, between Zagreus, the Olympians, and other residents of the Underworld on every run. For instance, Zagreus may meet Eurydice during a run, and when returning to the main house may meet Orpheus, and because the player met Eurydice prior, he may ask to have a message delivered to her, creating another chain of events that the player can seek to uncover.

Successfully escaping the first time will not end the game's story, the player must go again to uncover what happens after that.

Game Mechanics

The game is presented in an isometric point of view. The game features four "biomes" that Zagreus must escape through. Notably, they are Tartarus, Asphodel, Elysium, and the Temple of Styx. When a player starts a run, they begin in a room outside the main house. Afterwards, the player must fight their way through a series of chambers and enemies. The layouts of each chamber are predetermined, though the order of the chambers, as well as the number and types of enemies in the chambers, are different in every run. In some cases, there are chambers in which there are no encounters with enemies; instead the player can shop, restore health, or meet a resident of the Underworld and gain benefits from them. Each level will contain a certain number of chambers as well as a boss. After clearing each chamber, the player will be presented with a reward, which is shown previously above the chamber door. These rewards range from gifts from the Olympians, improvements for those gifts, currency for renovating the main house, upgrades for Zagreus's weapons, keys, and skill-point currency called "darkness" to improve Zagreus' attributes. If Zagreus' health points reach zero, he "dies," and emerges in the main house again. Any gifts granted on a run, besides currency, darkness, and keys, are lost upon death.

The player has six unique weapons to choose from before beginning a run. The player will be able to perform a primary attack, a special attack, and a magic spell. Each chamber has the possibility of earning a reward to upgrade Zagreus' weapons via Daedalus' Hammer. These upgrades range from having more range or damage on a weapon or completely changing how the weapon attacks. Each chamber also has the possibility of granting an aid from an Olympian, called a "boon." These boons improve the attacks of Zagreus based on the theme that each Olympian has. For instance, grabbing a boon from Zeus will grant Zagreus electrifying attacks and abilities, or Aphrodite will grant the "Weak" status, causing enemies to do less damage to the player. Sometimes dialogue between two gods will ensue after picking up their respective boons, and the player will be able to select a combined boon from them. The player also may choose a boon that enables Zagreus to call upon a god's aid when his "God Gauge" bar is filled to a certain amount. Players can mix and match different boons, upgrades, and weapons to optimize their run.

Before starting a run, players can choose and upgrade which attributes Zagreus will have via the Mirror of Night. These are upgraded through darkness and are permanent through each run. For instance, players can choose to add more health, add an additional dash, or add more casts for their magic spell. The player can choose to reroll their darkness to create different combinations of these attributes. They are also able to upgrade their weapons when they have progressed through the game enough and have the materials to upgrade them. The materials can be obtained through defeating the bosses on each level.

After successfully escaping the first time, the player will have the opportunity to ramp up the games' difficulty to earn more rewards via the Pact of Punishment. Through this, a player can turn up the "heat gauge" and add constraints to themselves, make enemies more difficult, and other "punishments." This allows for refreshing re-playable gameplay, and players can test and improve their skills. If players are more geared towards progressing the story, they can choose to enable "God Mode" which makes them stronger on every run.

Reception

The game has been praised for its marriage of "fantastic combat" and engaging story (Macgregor 2020). Vazquez (2020) highlighted that "Hades' narrative is so entwined with its combat is nothing new for the developers at Supergiant Games, who've established themselves as masters of putting your actions in sync with the stories they tell." Supergiant Games' previous game *Bastion* also garnered attention for its combination of gameplay mechanics and branching storyline (Mitchell 2016). As of November 2020, the game has a Metacritic score of 92 out of 100. (https://www.metacritic.com/game/pc/hades)

Islam; Islamic calendar; Islamic prayers; Medical robot; Muslim beliefs

Definition

Artificial Intelligence	Artificial Intelligence (AI) refers to the simulation of human intelligence by machines, especially computer systems.
Decision Support System	Decision Support System (DSS) is the specific application of AI used to support decision-making activities.
Computer Vision	Computer vision is the Artificial Intelligence (AI) system incorporated with other scientific fields, such as signal processing and Neurobiology, to interpret and gain high-level understanding from digital images or videos.
Healthcare Robot	Healthcare robot refers to a machine programmed by a computer capable of assisting humans in the medical field. In addition, it is able to provide care and support to disabled patients and the elderly.
Islamic Practice	Islamic practice refers to five pillars of Islam, which include the statement of faith called "shahadah," daily prayers called

"salah," almsgiving called "zakat," fasting during the month of Ramadan called "sawm," and at least once-in-a-lifetime trip to Mecca called "hajj" (Stefon 2009).

Introduction

People in today's world suffer from various health problems, and as a result, the demand for medication and healthcare services has increased. For example, people suffer from chronic diseases and require continuous medication. There is an issue for a patient to forget and skip their medication routine, for example, an elderly person. Therefore, an automated system for dispensing medicine is essential to avoid the issue. A healthcare robot can autonomously deliver medicine to patients at a scheduled time. As a result, the healthcare robot should also take care of the patient and ensure that the medicine is taken for the most effective treatment.

Motivation and Background

The healthcare industry plays a more critical role in providing effective healthcare treatment to patients at home. The idea of healthcare robots has become a significant invention in this field. Muslims believe that illness and pain are tests from Allah and perceive illness as a trail by which one's sins are removed (Kemp 1996). Therefore, healthcare providers need to understand the Islamic culture for clinical practices in Islamic families. For example, a nurse of the same gender should be cared for, especially when the patient is a female (Alotaibi 2021). Many issues need to be considered in the process of delivering culturally competent care to Muslim patients. These issues affect the design of the Decision Support System (DSS) with computer vision to decide the optimal action the robot needs to perform on Muslim patients. Currently, the standard robots are integrated with cameras that can capture both image and video. Computer vision technology is applied in the healthcare robot to recognize the patient and understand the current situation around the patient. Understanding the current situation will decide the appropriate action that the healthcare robot should interact with patients (Ic et al. 2013). Healthcare robots are programmable to provide medication service to patients at home. For example, one can schedule a robot to deliver medication pills to patients at home. In Muslim society, prayer is the second pillar of Islamic belief. Praying is the most fundamental worshiping practice that Muslims are obliged to take a certain number of times a day (e.g., five times). In general, Muslims can pray at any time of the day for distinct reasons (e.g., busyness, travel, etc.). Therefore, a healthcare robot with the ability to detect prayers by posture recognition is essential for Islamic families. Thus, the robot should recognize a person's posture and approach the patient with Islamic practices. An Islamic-cultural aware robot will significantly improve the robot medication service while also demonstrating respect for Islamic traditions.

Related Works

The first commercially assistive robot is Handy1 (Topping and Smith 1999). Handy1 is controlled by a single switch input for selecting the appropriate action. The Neater Eater assists patients with their meals, including scooping foods from plate to patient's mouth (Song and Kim 2012). Exact Dynamics' iARM technology is applied to assist disabled patients who cannot produce arm movements (Ghobreal et al. 2012). The robot arm is attached to the electric wheelchairs, allowing the patient to control the arm via the controller. The RAVEN II is a laparoscopic device created with objective clinical measures in mind to optimize surgical performance (Hannaford et al. 2013). MiroSurge is being developed by the German Aerospace Center (DLR) to be very adaptable in terms of the number of surgical domains, arm-mounting sites, a number of robots, control modes, and capacity to integrate with other technologies (Hagn et al. 2010). The ARMAR III is developed to assist patients in a household

environment, such as interacting with people and manipulating household items (Asfour et al. 2006). Care-O-Bot 3 is a robot for assisting people in their daily lives (Reiser et al. 2009). A flexible torso enables butler-like motions such as bowing and nodding, an arm and gripper for manipulating items, a tray for carrying and transferring goods, and a tray for holding and moving objects. As mentioned above, most robots are trained to respond to specific duties to assist patients. As a result, there has been considerable advancement in the ability of healthcare robots to perform medical services while also exhibiting respect for patients' cultural and religious values, such as in Islamic nations.

Structure of Learning System

The system architecture of healthcare robots is described as follows. The healthcare robot usually sends the data to the Robot Decision Services (RDS) for deciding which action the robot should take. The decision system on RDS consists of three subsystems: the Face Recognition System, the Prayer Time Decision System, and the Prayer Posing Detection System. These three subsystems will cooperate to determine the optimal action for the robot. The optimal action will be sent back to the robot along with the action code. The description of subsystems is presented as follows: (1) Face Recognition System (FRS) is responsible for recognizing the patient's face from the given image. The clear face image of users must be first submitted to the system. Technically, all face images are encoded in high dimensional space so that the distance between two vectors represents the similarity of two different face images. All face vectors are recorded in the Face Database. (2) The Prayer Time Decision System (PDS) is responsible for decision-making on the prayer time. It annually updates the Prayer Time Database from the public Islamic calendar service. PDS is required in this system because the robot should not interfere with the user during prayer time. The system also supports any time zone and adds the predetermined offset time to each praying schedule. (3) Prayer Posing Detection System (PPDS) is responsible for detecting and recognizing the posing of the patient. It analyzes the image and determines the posing of the patient at any time of the day. Object detection techniques are used to detect four main postures in Islamic prayer, Qiyam, Ruku, Julus, and Sujud, but it should also be able to distinguish the four main postures from traditional postures. For example, body centroid detection is used to identify whether the human object is moving and avoid false detection on similar posture such as walking/standing as Qiyam and sitting as Julus. A machine learning model should also be implemented to detect and recognize some restricted posing set, such as lying down, standing up, sitting down, and walking.

The process of healthcare robots is described as follows. When it is time to take medicine, the robot will continue searching for the patient in the house. If the user is identified and located, the robot will send the request to RDS to determine the optimal action in real-time. The request data that is sent to the server consists of the image from the camera sensor and the timestamp. Technically, the images are converted into string format before sending through the network connection. Then, the robot will act upon the decision response from the server.

The process of RDS is described as follows. RDS can be considered a server-side web Application Programming Interface (API). RDS listens for the request from the robot. After receiving the data from the robot, RDS will check the validity of the request message. If the request message is not matched, the server will send the error message back to the robot for collecting new data. Then, the image is decoded and sent to FRS. If the face in the image is not the targeted patient, RDS will send the message to inform the robot that the following action is to continue searching for the patient. RDS will then check for the prayer time by considering the image's timestamp, current time zone, and praying schedule. If the timestamp is between the praying time interval, the system will go to a room to search the patient. However, the prayer time may differ from the praying

schedule for many reasons. The system also determines the current action of the user to avoid interference in between the praying processes. The current action of the user can be determined from the image. If the praying pose is detected, the system will wait until the patient finishes Islamic praying.

Hearthstone: A Collectable Card Game Through the Lens of Problem Solving

John Scott[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Collectable card game

Definitions

Collectable Card Game = a type of strategy game where players collect cards to form a custom deck to overcome challenges presented by other types of decks.

Introduction

Hearthstone is a collectable card game that does a good job of showing the lens of problem solving, which is all about the problems that a game poses to a player, and how the game continues to make the player solve new problems. In Jesse Schell's

book "The Art of Game Design: A Book of Lenses," the Lens of Problem Solving states that "To use this lens, think about the problems your players must solve to succeed at your game, for every game has problems to solve." (Schell, 2019) The Lens of Problem Solving requires us to ask the following questions:

1. What problems does my game ask the player to solve?
2. Are there hidden problems to solve that arise as part of the gameplay?
3. How can my game generate new problems so that players keep coming back?

Gameplay

In Hearthstone there are two main ways to play, multiplayer (which includes ranked and unranked) and solo adventures (which include raids and challenges), both of which have a max card limit of 30. In solo adventures, the developer directly interjects the problem solving, rather than allowing it to fall unto the players to create and solve problems for each other. The main content in solo adventures is raids, which pits the player up against a variety of bosses with varying difficulty, and challenges, where the player is put against a group of weaker enemies while also having less choice on how they're going to approach the enemies. With raids, players make their own decks around each individual boss, while with challenges, the player is given a deck, and as they progress through enemies they are given more cards and gameplay options to mix with their existing deck to make as strong a deck as possible to defeat the later enemies.

Raids require the most direct problem solving. The game puts a boss with a unique ability and unique move set in front of you and you have to build a deck around that. This can lead to some insane decks being made. A good example is one of the earlier bosses in the Icecrown raid; this boss has 30 health (a normal amount), and a free, spammable ability that allows him to go back to 30 health every turn. So, the problem is how to defeat an enemy that can heal so much damage for free. The solution is simple in concept but difficult in execution. Dealing 30 damage in a single turn. Some classes have it easier than others. Priests, for example, can just put a high health minion onto the field, increase its health to be at or above 30, then set its attack to be equal to its health, allowing it to just one shot the boss. While other classes, like mages, have to set up intricate combinations of cards, one example being having cards that reduce the mana cost of a spell and another card that allows you to cast that card until you run out of mana. The real challenge there being that you have to get quite a few cards out at the same time or risk having important cards being destroyed before you can use them.

Challenges start the player with a smaller deck to work with, but also place them against much weaker opponents. After each opponent, you choose between three sets of three new cards that you add into your deck. These cards ignore the normal limitations of the game, allowing you to have more than two of the same card. On top of this, after the first and fourth enemy defeated (out of eight), you are given the option to choose a buff. These buffs can be anything from increasing your health significantly, or giving you extra mana at the beginning of the game. With the way challenges are set up, the problem solving is less reliant on the cards that you personally own, and more reliant on your own skill and knowledge of the game as a whole. However, it does introduce a luck element, where you might not get the most optimal options, and struggle because of it.

Multiplayer Mode

In the multiplayer mode, the game is constantly updated with new cards and interesting meta-breaking combinations to find, so you get your average competitive game where both players are set against each other with plenty of opportunities to outplay the other. The ranked mode has 25 ranks that you have to go up before you can reach the "legend" rank, and start playing to be placed as one of the best players in the world.

In closing, Hearthstone has the entire problem solving of a multiplayer game mixed with varied

and difficult single-player content that can be very challenging to figure out. It has a very large amount of cards to make new strategies and there will always be something that requires a new deck to beat.

High-Performance Many-Light Rendering

Tong Wang
Cygames, Inc., Tokyo, Japan

Synonyms

Many-light rendering; Virtual point light

Definitions

Many-light rendering is a class of efficient image synthesis algorithms that try to render a scene with a large number of light sources. These light sources can be real lights in the scene, or virtual point lights (VPLs) approximate light transportation of current lighting conditions.

Introduction

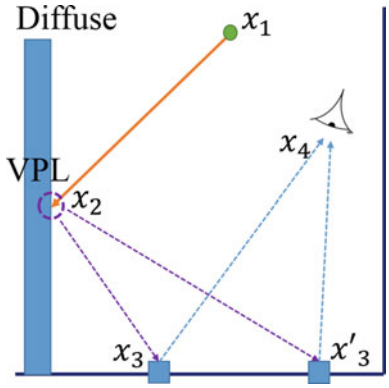
Full global illumination is considered the crown of rendering. Creating high fidelity global illumination efficiently is one of the most important topics in photo-realistic image synthesis. In order to calculate a high dimensional integration in the rendering equation proposed by Kajiya (1986), a huge amount of computational power is needed, which prevents the pure path-tracing group of methods from implementing in an interactive to real-time systems. In the other hand, such tracing algorithms are often not regular, which will cause workload balance problems or irregular memory access problems on parallel hardware architectures especially current GPUs, thus harm the scalability of the algorithm.

In this entry, we will introduce many-light rendering, which is one of the simplest and most elegant solutions in the global illumination field that can increase scalability while still being able to generate photo-realistic images. The main idea of many-light rendering is to split the rendering into two steps: The first step is to generate a massive amount of virtual-point-lights (VPLs) in the scene according to the original rendering equation or path space integration framework proposed by Veach (1997). The second step is that for each pixel, the irradiance will be collected and accumulated from all VPLs to approximate the final results. Among all the physically based rendering techniques, many-light rendering methods are considered best suitable for fast preview and iteration situations, which are also often suitable for GPU-based parallelization scheme.

Many-light rendering algorithms can also be applied in a scene with a large number of actual light sources, which is becoming more and more common recently. Scenes illuminated with numerous actual light sources can also migrate algorithms from the VPL-based global illumination algorithms. Some recent advances can be found in literatures such as Dachsbacher et al. (2014), Bitterli et al. (2020), and Yuksel (2020).

Many-Light Rendering: Paths in VPL Framework

Keller (1997) is considered the beginning of many-lights rendering. VPLs are generated by



High-Performance Many-Light Rendering, Fig. 1 Illustration of the generation of VPL. A VPL x_2 is generated from the light source point x_1 during generating step. It will then illuminate other surface points such as x_3 and x_3. It will be collected to the pixel plane point x_4 on the camera

light path random walk in the scene. Figure 1 is a simple illustration of such a VPL path. For the *i-th* VPL x_i generated by vertex x_{i-1}, among total VPL number of n, and an eye vertex x_e, the radiance reflected at eye path intersection point (also referred to shading point) $\overline{x}$ is:

$$L = \sum_{i=1}^{n} f(x_{i-1} \rightarrow x_i \rightarrow \overline{x}) \\ \alpha_{x_{i-1}} G(x_i, \overline{x}) f(x_i \rightarrow \overline{x} \rightarrow x_e)) \quad (1)$$

where L means radiance coming to eye vertex $L(\overline{x} \rightarrow x_e)$, $G(x_i, \overline{x})$ is the geometry term containing the visibility term $V(x_i, \overline{x})$. $\alpha_{x_{i-1}}$ is the virtual light contribution of vertex x_{i-1}, which is defined as a Monte Carlo style sampled path contribution of a random walk path sequence generated from the light source.

The two steps of a VPL-based many-light rendering are

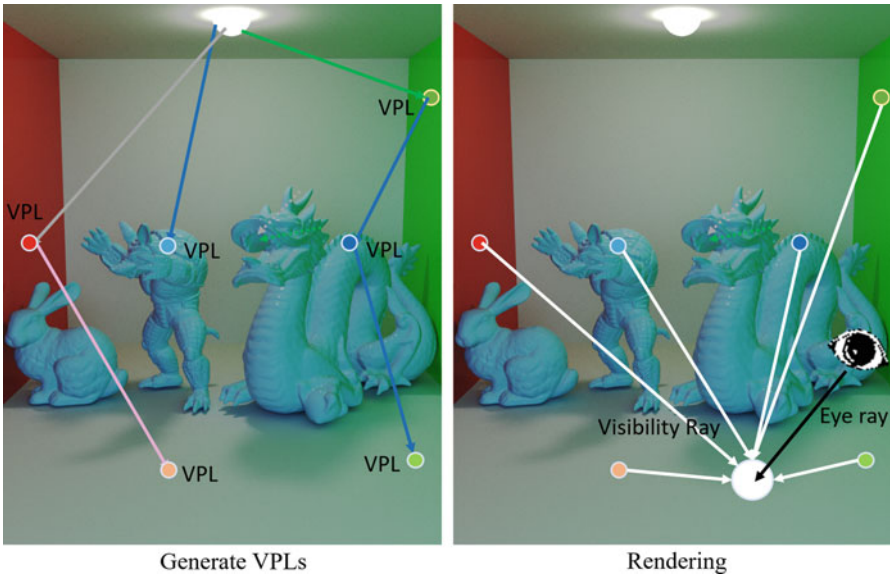
- Generate a large amount of VPLs in the scene. Choose the light sources and starting position randomly, then shoot a VPL ray from the point into the scene. If the intersection surface is diffuse, record the VPL with corresponding probability, BRDF (Bidirectional Reflectance Distribution Function), and geometry term on the scene. Trace the ray with a Russian roulette termination condition.
- For each rendered point, collect illumination from all VPLs. Iterate each VPL and conduct a visibility test to determine if the VPL is visible from the rendered point, then compute and accumulate the contribution from each VPL.

Figure 2 is a simple illustration of such two steps.

Another situation that needs to calculate a huge amount of light is when there are actually many light sources that exist in the scene. These two problems share a similar computing model, thus are often classified in the same category. To distinguish these two different end applications, we refer to the VPL-based global illumination scenario as many-light GI, and the second scenario as many-light DI (direct illumination from actual light sources).

The first step of many-light GI is to distribute VPLs in the scene. There is a lot of research studying how to efficiently distribute VPLs in the scene. Georgiev and Slusallek (2010) introduced a simple reject-sampling method that will filter out unimportant VPLs. Hasan et al. (2009), on the other hand, are trying to generate virtual light sources that can avoid the singularity problem, which will cause bright spot artifact in the final rendered results.

For the second step, our problem is more clear: how to efficiently accumulate energy from a massive amount of virtual point lights distributed at various regions in a complex scene geometry. The basic method is to calculate the color of N samples, from every light source (VPLs or actual light sources) of a total number M, which indicates at least $M * N$ raycast and lighting calculation. The $O(N * M)$ algorithm is not acceptable when there are massive samples on the pixel plane and a large number of light sources in the scene, especially for interactive and real-time applications. So we need to make approximation or calculate the accumulated energy in a clever way to reduce the cost and increase the scalability of the algorithm.



High-Performance Many-Light Rendering, Fig. 2 The two steps of a general VPL-based illumination

High-Performance Many-Light Rendering

From the previous section, we know that to gather the full lighting information for a specific point in many-light rendering, a huge number of raycasts will be performed to calculate the visibility between the shading point and light sources.

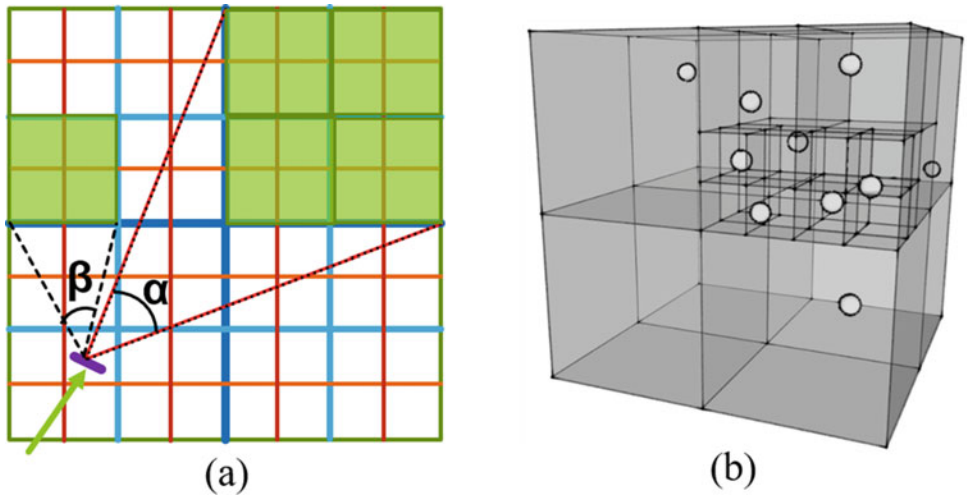
Cluster-Based Method

An observation is that samples and light sources (or VPLs) that are near to each other often share similar visibility and lighting information. A natural idea that can help to solve the performance problem is to cluster nearby similar VPLs together to form stronger lights to decrease the necessary number of visibility raycasts (Fig. 3).

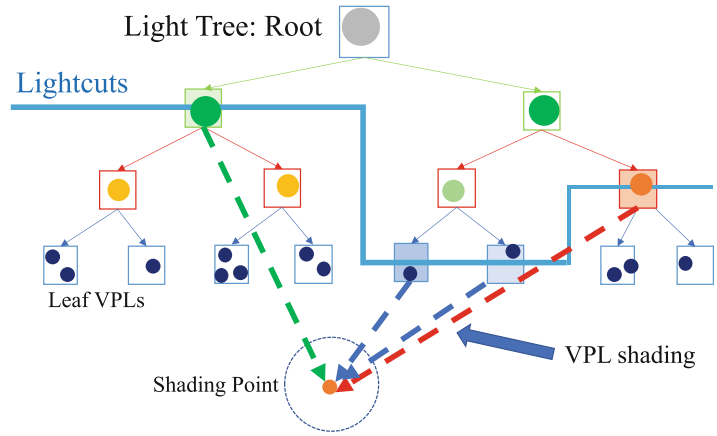
Walter et al. (2005) is an early work on the approximation of VPL clustering. All lights or VPLs will be constructed into a tree structure called a light tree. A light cut means all the nodes that have been chosen for a specific shading point. Figure 4 shows how a shading point is illuminated by a hierarchically constructed light tree. From a certain shading point's perspective, the visibility and contribution of faraway nodes less than a threshold solid angle will be calculated as a whole to reduce computational cost. The nearby lights that exceed the solid angle threshold may need to be calculated separately to increase the accuracy of the illumination.

Other works such as Ou and Pellacini (2011), Walter et al. (2012), and Bus et al. (2015) dive into this idea further by exploring theories and techniques to cluster shading points as well. The scalability of many-light rendering methods is significantly improved with these hierarchical cluster-based methods.

Another important group of techniques that tries to cluster lights and shading points by another formulation is the Matrix Row-Column Sampling (MRCS) method proposed by Hassan et al. (2007). It formulates the many-light rendering problem into a matrix row-column sampling problem from the VPL evaluation matrix M. The row of M is all the shading points, and the column of the matrix represents all the VPLs. Thus, the entry $M(i, j)$ is the contribution from VPL j to the shading point i. Hašan et al. (2007) observed that matrix M is often low rank, which means that it can be compressed to a smaller matrix. Shading points and VPLs will be clustered through the



High-Performance Many-Light Rendering, Fig. 3 (**a**). VPLs can be clustered together with a certain error-bound constraint, thus the similar project angles from different distances. VPLs can be clustered together with a certain error-bound constraint. (**b**). Octree is a famous spatial subdivision structure that can be used to construct such light tree



High-Performance Many-Light Rendering, Fig. 4 Light cut of a light tree. The shading point will be shaded by the nodes and leaves on a specific light cut calculated with error bound

compressing algorithm. To do such a compress, the author proposed to do a row-column sampling algorithm that can effectively create the low-rank matrix which can be evaluated efficiently.

Huo et al. (2015) is a matrix-sampling-and-recovery scheme developed from MRCS that aims to efficiently accumulate the illumination contribution by sampling and reconstructing the low-rank illumination matrix as well as predicting visibility from spatially correlated shading points and lights. Huo et al. (2016) explore the locally coherent nature of scattered lighting in heterogeneous media. Nabata et al. (2016) proposed an error estimation framework for such a clustering scheme.

Sampling-Based Method

Clustering lights together is a biased approximation with a bounded error, which may not meet the demands of high-quality-image-synthesis tasks. To generate unbiased synthesis with a huge amount of light sources, an unbiased Monte-Carlo integrator is needed. There is a group of methods that try to find important lights through sampling in an unbiased way, and here we will

introduce some of the important works developed recently.

Moreau et al. (2019) proposed the many-light sampling method that maintains the hierarchical light sampling data structures. Light sources are organized in a bounding volume hierarchy (BVH). They will be stochastically traversed during the shading phase. Lights maintained in a two-level light acceleration structure will be stochastically selected by evaluating an important function. They achieve two orders of magnitude faster than the original off-line implementation.

Yuksel (2020) presents a stochastic light cuts technique that can replace the sampling correlation of light cuts and replace it with noise to resolve bias issues in light sampling. The basic idea is that for each node in the light tree, choose the representative light in a stochastic way to avoid extra bias. They will also be chosen on the fly to avoid extra storage of light tree. Yuksel also developed a hierarchical importance-sampling scheme that can compute the light probabilities using the light tree during the lighting evaluation at a given point on the fly.

A recent important work is Bitterli et al. (2020). This work proposed a spatiotemporal reservoir-resampling method that can be applied in many-light condition. The main idea is based on a resampled importance sampling (RIS) technique that can effectively reuse statistics from temporal and spatial neighbors for each pixel's direct light sampling PDF. Combining with a biased estimator, this work will be able to synthesis photorealistic images for scenes containing dynamic emissive triangles on GPU in real time.

Conclusion

In this entry, we introduced the basic theory and techniques about an efficient set of algorithms for photorealistic global illumination: many-light rendering problems. We summarize cluster-based and sample-based methods that can improve the efficiency of this algorithm significantly. Both came with a price: The cluster-based methods generate an approximation of the global illumination with a bounded error by traversing hierarchically constructed light tree or shading point tree but will bring extra bias to the final results, while the unbiased Monte-Carlo estimator sampling the light source will be able to generate unbiased results but will bring noise due to the variance which may not be suitable to use directly for interactive applications. In practice, these two groups of methods can be combined together to leverage accuracy and performance.

Synonyms

Augmented reality; Computer-mediated reality; Mixed reality

Definition

A form of computer-mediated reality that superimposes images into the view of a user. It uses the existing environment, complementary imagery, and interactivity to bring an enhanced experience.

Introduction

Augmented reality is a form of technology that falls under the category of computer-mediated reality. Like its fellow technologies, such as virtual reality, this technology allows users to interact in a computer environment. This technology, however, allows users to interact within their existing world, instead of a fully immersive one. Only a few decades old, the technology still has had an interesting path to its more mainstreamed state that we enjoy today.

History of Augmented Reality

The first reference to Augmented Reality technology is said to come from the author of *The Wonderful Wizard of Oz*, Lyman (L.) Frank Baum in 1901. From another work of Baum's called *The Master Key*, a demon provides a character with the "Character Marker" – which is a pair of spectacles that would place a "G" or "E" on the foreheads of each person that they would meet, which correlated to whether they were good or evil. There was also "W" for wise, "F" for foolish, "K" for kind, and "C" for cruel. When asked who discovered the device, the demon informs the reader that: "It is a fact that has always existed, but is now utilized for the first time." (Javornik 2016)

Much like the virtual reality, some of the technologies that brought augmented reality to life overlap and have existed before the creation of the specific technology itself. In fact, these technologies such as virtual reality, augmented reality, and others are contained on a spectrum and can be referred to as mediated reality. Two less recognized forms of this mediated-reality space are modulated reality and diminished reality (Grover 2014). Overall, what this field of mediated reality allows for is the ability of the computer to add or subtract from our perceived reality – adding into the experience until it is completely immersive, such as in virtual reality.

Similar technologies that fueled the development of virtual reality also lay behind the inspiration for augmented reality. In 1929, Edward Link created the "Link trainer," which was an

electromechanical flight simulator that encapsulated the individual into a replica cockpit. During WWII, 500,000 pilots improved their skills by logging hours of initial training on 10,000 "Blue Box" Link Trainer machines. Later, the Sensorama was created in the mid-1950s by Morton Heilig, a cinematographer that patented the device later in 1962. It had stereo speakers, a stereoscopic 3D display, fans, smell generators, and a vibrating chair. Using his background in cinematography, six short films were created by Morton Heilig himself to accompany the device.

In the 1960s and 1970s, more advancements were made on the technological front of these industries. These include a continuation of Morton Heilig's work within a device called the Telesphere Mask in 1960. More attention was beginning to be paid as a pair of Engineers from Philco Corporation, Charles Comeau and James Bryan, created the Headsight in 1961. It was developed for immersive, remote viewing of dangerous situations by the military. The 1960s also saw the writing of the Ultimate Display concept by Ivan Sutherland. His design housed a computer-generated virtual world that was maintained in real time. The 1965 paper laid the foundation for concepts that represent the core blueprint for these types of mediated reality technologies today. However, it was not until recently that Augmented Reality began to take off.

The 1990s is when Augmented Reality truly came into fruition. The term was first coined that year by Boeing Engineers' Tom Caudell and David Mizzel (Rauterberg 1990). This is one year after virtual reality received its official title from Jaron Lanier. From the coining of its term in 1990 and every few years, major developments were made. It was in 1992 with Louis Rosenberg that steps were taken towards a functional augmented reality system. It was called Virtual Fixtures and was developed through the US Air Force Research Laboratory. His research showed that an AR system could enhance performance. Rosenburg is dyslexic and attributes some of his success in technology to this trait. In fact, his issue with handwriting is what spurred him towards the computer in the first place (Rosenberg 2016). He continued his research at Standford University, showing further proof that virtual overlays helped the user interact in the real world with enhanced capability. His moral underpinnings as an animal rights supporter and vegan mostly likely aided in his passion as he later develop the first VR surgical simulators that helped to reduced the use of animals for medical training (Rosenberg 2016).

In 1994, Steve Mann, recognized more as the father of wearable computing, also cemented himself into the fathering of augmented reality with his invention of the Digital Eye Glass and mediated reality. (Mann 2018) At one time during work at MIT, he would wear 80 pounds worth of equipment to class as he worked on wearable technology and interacting technology with the environment (Mann 2013). A believer that technology should be organic to humans, rather than humanity learning the ways of computing, inspired him to integrate these two worlds.

In 1996, Jun Rekimoto invents the 2D matrix markers for AR objects, also known as CyberCode. It is a technique that allows for augmented reality to identify real world objects and estimate their place in a coordinate system. The technology uses barcodes to identify large numbers of objects. This additionally makes it so that objects can have useful information associated with them when interacted with. The technology kept on maturing as the decade ensued. One year before the millennium in 1999, Hirokazu Kato created ARToolKit at HITLab, which started an open source computer tracking library that created augmented reality applications that could be placed into the real world.

The first augmented reality game was created by Bruce H. Thomas and was called ARQuake. It was demonstrated at the international Symposium on Wearable Computers in 2000. Smaller developments were made in the technology that continued to bring it to more market appeal, but it was not until 2013 with the announcement of Google Glass that the technology began to gain more mainstream hype. Even the Google Glass creation was met with some criticism, Steve Mann said during the Augmented World Expo in Santa Clara that the technology was more a generation one device, similar to other prototypes of the past (Hollister 2013).

What was the moment that sent AR over the edge? Well, one could say that it was the breakthrough phenomenon of the Pokemon Go game that allowed the technology to spread its wings in the full twenty-first century – at least in a household use sense. We may begin to see more inclusion of interesting advancements in augmented reality, as it has been dubbed the eighth medium – coming on the heels of mobile technology, internet, TV, radio, cinema, recordings, and print. This technology will be used in multiple ways, as it is expected that one billion people will begin interacting the technology by 2020. The Microsoft Hololens was finally delivered in 2016 after its initial introduction in 2015; the developer's kit is now available and the technology is seeking to upend some of the ways that we have traditionally approached augmented reality.

The technology places images and objects into the environment to interact with and is dubbed by Microsoft as a mixed reality system. There are exciting developments surrounding the technology, for example, an individual could see through your device to guide you through a repair job (Statt 2015). One could also Skype with another person and walk around freely, and not worry about having their full field of view obstructed. The device also presents educational, gaming, and a fundamental change in how computing is expected to interact – as the system is completely self contained and independent from an underlying computer. This is unlike virtual reality systems like the Oculus Rift that tether you to a desktop computer and corrals the users within the range of sensors.

What augmented reality will provide is an exciting link between traditional computing interactions and the real world. There is the ability to try on clothing or glasses before you purchase them from an online venue or store, or to try on several outfits at the drop of a hat. There are educational advantages and integration into our self-driving car future. As more recent phones from Google, Apple, and the like begin to integrate more augmented reality into their latest releases and software updates, then there will come a plethora of new applications and interactions within the technology.

These mediated reality technologies are set to make $162 billion by 2020 (Intelligence, BI 2016). This growth is poised over the distribution of the technology itself, as it does require hardware purchases. The wearable market, which slightly overlaps in this technology, is estimated to sell $34 billion dollars worth of devices by 2020, compared to the $14 billion in 2016 (Lamkin 2016). The industry is on the rise and as we continue to integrate incredibly more powerful watches, glasses, and cell phones into our daily lives, then there is a way this technology could deepen the experience already enjoyed. Perhaps one day, built into every pair of glasses could be a "Character Marker," as first forecast in 1901 and already in use in some facial recognition smart glasses today.

History of Virtual Reality

Mehmet Ilker Berkman
Communication Design, Bahcesehir University
Faculty of Communication, Istanbul, Turkey

Definitions

The term "virtual reality" was coined by Jaron Lanier in 1987 during a period of intense research in immersive technologies (Virtual Reality Society 2017). Lanier owned a research company pioneered in 3D graphics and immersive interactions that produced the first commercially available virtual reality equipment such as virtual reality glasses and data gloves.

Some of the artifacts mentioned in this entry for an historical account of VR (virtual reality) are dated far earlier than 1987, since they were chosen according to criterion that the artifact creates an immersion effect primarily based on sense of vision. Using a technology-oriented approach in relation with the arguments in contemporary research, Garner (2018) suggests that stereoscopy, field of view, and synchronized multimodality are vital contributors to presence and immersion which are two of the most significant elements of VR experience. To enhance immersion and presence, an artifact may also employ auditory, olfactory, or somatosensory stimuli besides 2D (two-dimensional) wide angle field of view or 3D (three-dimensional) vision.

While the definitions given here were limited to the technical progress, devices, and products in relation to VR; some authors (Gigante 1993; Jerald 2015; Steinicke 2016) mentioned the fictional representations of the virtual worlds in literature, cinema, and television as a part of VR history.

History

Mechanical Precursors

History of VR (virtual reality) can be taken as far back to 1793, when the Irish painter Robert Barker exhibited his panoramic paintings at the rotunda in Leicester Square, which is the first building purposefully constructed to view the paintings located on the inner facet of circular walls, with internal staircases and platforms (Benosman and Kang 2001). The building itself is an immersive technology, patented in 1796 by Barker. It is followed by a sequel of similar display methods such as Franz Niklaus König's Diaphanorama, Daguerre's Diorama, Charles A. Close's Electronic Cyclorama, Thomas Barber's Electrorama, Lumière Brothers Photorama, and Grimoin-Sanson's Cinéorama (Uricchio 2011). The Cinéorama, appeared in 1900 Paris

Exposition, consisted of ten synchronized 70 mm motion picture projectors screening a 360° moving images on the walls of a circular space, where an audience of 200 viewers can be located at the center in a gondola-shaped platform to experience a balloon ride over Paris. Some other immersive setups in Paris Exposition were Trans-Siberian Railway Panorama and the Mareorama, both used moving panoramas painted on canvas to simulate motion within traveling experience. The nineteenth century panorama evolved into a mass media while people around Europe visited various panoramic displays immersing themselves in views of nature, landscape, and historic events (IJsselsteijn 2005). These circular display techniques of panoramic vision evolved into widescreen cinema in twentieth century.

Stereoscope was another early invention of nineteenth century that pioneers virtual reality technology. In 1838, Charles Wheatstone, Professor of Experimental Philosophy in King's College (London) devised two mirrors located at 45° to the viewer's eyes, reflecting two slightly similar images. Images were drawings, since it was a year before Daguerre (who was also the director of Dioroma mentioned above) established a practical photographic process called daguerreotype. Later in 1841, Wheatstone made experiments with photographs taken with a single lens camera from different angles (Wade 2012). In 1849, David Brewster has developed a handheld stereoscope using prismatic lenses besides a binocular camera to take stereoscopic photographs. Brewster (1856) credits the first functional stereoscope to Mr. Elliot's design in 1834, which is a stereoscope that does not employ any mirrors or lenses: the ocular stereoscope. Referring to Wheatstone's device as reflecting stereoscope, Brewster named his own invention as lenticular stereoscope. The Brewster stereoscope had drawn a huge public attention. A London based company sold more than half a million stereoscopic views from 1856 to 1858 and a million views in 1862 (Bendazzi 2016: 15). The public attention in stereoscopes led to attempts to combine stereoscopic views and motion, such as Claudet's and Duboscq's efforts in 1852, which was the earliest patent application for a motion-picture stereoscope (Wade 2012; Zone 2014: 26). However, neither of these attempts for a motion-picture stereoscope resulted with a commercially successful product, due to the "contrast between the ease of inducing apparent motion and the difficulty of seeing depth in sequences of briefly presented stereoscopic images" (Wade 2012). Stereoscopes stayed in use until early 2000s as an entertainment and educational technology and finally a children's toy, to view stereoscopic images printed on cards, film, slides, and reels. The design of Brewster evolved into phone-based VR products after 2014, which employ mobile phone screen to show stereoscopic images instead of printed images (Jerald 2015: 16).

Stereoscopic projection artifacts should also be mentioned within the early efforts that can be related to virtual reality. Louis Ducos du Hauron, the inventor of color photography, enhanced the "anaglyph" methods that can also be used for forming three-dimensional visuals based on encoding each eye's image using filters of different colors. The term "anaglyph" was first used by de Hauron in 1890s, but the principles were known since as early as seventeenth century (Zone 2014: 55). The first stereoscopic projection based on anaglyph method was described by Wilhelm Rollman in 1853, who could have been the first to project images with complementary colors but the first projector that is known to be actually built was made in France by Charles d'Almeida, in 1858. In nineteenth century, the methods based on the polarization of light were also employed to display three-dimensional images. The principles of polarization had been known since seventeenth century, but a British physicist named John Anderton is credited to be the first to use it for projection of three-dimensional images with his mechanism patented in 1895.

Immersive Movies

During the first two decades of twentieth century, motion pictures became a popular entertainment medium. However, until 1922, there was not a successful product of 3D motion pictures that has developed beyond prototype stage. In September 1922, the first 3D feature film, *Power*

of Love, was screened to an invited audience at Ambassador Hotel Theater in Los Angeles. The film is taken by Harry K. Fairall's camera which was later patented as "Binocular Nonstop Motion Picture Camera" in 1930. Stereoscopic viewing was achieved using anaglyph method, in which viewers use complementary colored glasses. Another anaglyph based 3D motion picture were Plasticons by William Van Doren Kelley's stereoscopic camera pair, followed by Jacob Leventhal and John Norling's Plastigrams, which were animated cartoons that obtained a large audience in multiple theaters. Success of Plastigrams created a demand for more novelty 3D film, which was filled with Stereoscopics created by Jacob Leventhal in 1925, followed by Audioscopics in 1935. Although the commercially successful examples of 3D cinema was based on anaglyph method, there were attempts to use alternate frame and polarized viewing technologies. The Teleview of Laurens Hammond was a public 3D motion picture screening in New York, in December 1922. This 3D motion picture system installed at Selwynn Theater used a twin-strip 3D camera with two lenses, dual projectors, and a revolving electrical shutter affixed to the armrest of each spectator's seat. The Zeiss Ikon company based in Dresden Germany used polarized 3D methods. Working in cooperation with the State Establishment for Physics and Technology of Braunschweig, Zeiss Ikon developed a high-speed twin 16 mm stereo motion picture film system for use at the Berlin Olympics of 1936; while in 1935, Otto Vierling developed a single-strip 35 mm stereo camera system using a prism in front of the lens for Zeiss Ikon, viewed using polarized glasses (Zone 2007).

Wide screens were alternative to 3D stereoscopic vision in order to create an immersive experience. In 1950s, the motion picture industry in USA was seeking for novelty in order to compete with television. Wide screen cinema was a solution to attract viewers to movie theaters. Developed in 1952, Fred Waller's Cinerama used three simultaneously shot 35 mm films that were synchronized and interjoined into a single wide image projected on a huge curved screen by three projectors, forming a 146°–55° viewing angle for the spectator. The curved screen consisted of vertical strips angled toward the audience to prevent light reflected from one edge of the screen to wash away the image on the other edge. Originally, Waller developed an 11 projector system called Vitarama for 1939 World's Fair in New York and worked on five projector systems for military training purposes during WWII. Although the wide screen technologies revoked the interest into movie theaters, systems like Cinerama, such as its successors Cinemiracle, Thrillerama, and Wonderama which were based on multiple cameras and projectors, were not widely accepted due to production and projection costs. The Cinemascope technology became popular, which is based on single camera and projection that uses an anamorphic lens to create a wide screen picture (Reeves 1982; Patterson 1973).

Norton Heilig brought the immersive viewing experience one step further, with his "Telesphere Mask" and "Sensorama." Patented in 1960 and 1962, these two inventions can be regarded as multisensory theater with 3D images, stereo sound, wind, smells, and vibrations, but the interactivity was missing (Bown et al. 2017).

Telesphere Mask was described as "Stereoscopic Television Apparatus for Individual Use" in patent documentation, with a pair of adjustable lenses, a pair of television tube units, a pair of earphones, and a pair of air discharge nozzles. Nozzles meant to provide air currents of varying velocities and temperature, with odor. Being a wearable device, Telesphere Mask highly resembles to the modern head mounted VR systems. However, it does not provide any motion tracking ability. Although Heilig actually build the device, he focused on a more advanced system. Sensorama, patented in 1962, was a device roughly equivalent in size to a video arcade cabinet, with a housing that holds a hood to fit the head of the observer, for viewing projected stereographic images through an optical setup. The hood also contains audio equipment and a breeze is directed toward to hood to enhance multisensory experience. Heilig created five films for Sensorama, a bicycle ride, a ride of a dune buggy, a helicopter ride over Century City, and a dance by a belly dancer, and a motorcycle ride in

New York city, which includes a vibrating seat, rush of air through observer's head with odors alongside the riding path. As this was the first olfactory stimulus embedded within an immersive technology, computer controlled olfactory interfaces were not available until 1993 (Youngblut et al. 1996). Heilig had the vision on the Sensorama's potential in education, training, and marketing but it was a commercial failure and the only instance of it was employed as an arcade console (Bown et al. 2017; Garner 2018). In the mid-1960s, he extended the idea to a multiviewer theater concept patented as the Experience Theater in 1969.

The Modern Age

As there are numerous developments in VR during modern era, these are given as sections instead of chronological order.

Head Mounted Displays

Built by Charles Comeau and James Bryan in 1961, The Headsight was a remote surveillance device that attaches a video camera to a head mounted display. It was not intended as an immersive virtual reality technology. For its motion tracking capabilities it is credited as a milestone in history of virtual reality, since it uses magnetometers to track head movements of the user to control the attached camera (Jerald 2015; Bown et al. 2017; Garner 2018).

In 1967, a civil and military helicopter manufacturing company tested a head-mounted display (HMD) that showed video from a servo-controlled infrared camera mounted beneath the helicopter. The camera motion is synchronized with pilot's head, both augmenting his night vision and providing a level of immersion sufficient for the pilot to equate his field of vision with the images from the camera (Fabri et al. 2008).

A technical report of a project in Wright-Patterson Air Force Base dated to 1969 is publicly available about the design of a helmet mounted display for US military pilots (Heard et al. 1969).

Ivan E. Sutherland envisioned a computer controlled virtual environment that emulates real-life physics in his classical article "The Ultimate Display" (Sutherland 1965). In 1968, Sutherland demonstrated his ideas with a prototype named "Sword of Damocles," a head mounted 3D display that is capable of presenting computer generated images to the user with a perspective image which changes as user moves. System employed special spectacles containing two miniature cathode ray tubes for stereoscopic vision; two head position sensors, one mechanical and the other ultrasonic, to measure the position of the user's head. The name "Sword of Damocles" comes from the mechanical head positioning sensor, a mechanical arm hanging from the ceiling. It is rather heavy and uncomfortable to use, and the ultrasonic solution was designed as an alternative. The display system was an augmented reality apparatus rather than a virtual reality device, since the images on cathode ray tube displays are reflected on half-silvered mirrors which allow user to see real-world objects in the room simultaneously. The images viewed by the user are transparent "wire frame" line drawings, due to the computational costs of rendering solid objects in real time. Although the objects viewed by the users are quite simple as a cubical room, Sutherland (1968) reports favorable response of users to good stereographic vision.

The origin of the contemporary VR HMD is based on the design of Drs. Mike McGreevy and Jim Humphries at NASA Ames Research Center. The system is called VIVED (Virtual Visual Environment Display), which later evolved into VIEW (Virtual Interactive Environment Workstation) as a general-purpose, multisensory, personal simulator and telepresence device, configured with head and hand tracking, monochrome wide field-of-view stereo head-mounted displays, speech recognition, 3D audio output, and a tracked and instrumented glove (Fisher et al. 1987) and has encouraged several American companies to develop related commercial products (Mcgreevy 1991).

An alternative to HMD's were boom-mounted displays, a stereoscopic binocular displays attached to a multilink arm. While the arms purpose was tracking the motion of user, it also helps to balance the display. Another advantage of this kind of setup is that suitability for turn-taking use for multiple people, i.e., when a user releases the

device, another person can take place and continue to view the virtual environment from the same perspective. Sutherland's Sword of Damocles was built around the same principle, while several boom-mounted displays were available as commercial products in 1990s (Youngblut et al. 1996).

Flight Simulators

The history of the mechanical flight simulators can be dated back to 1910, but the foundations of modern day flight simulation were based on Edwin Link's work (Allerton 2009). Based on the simulator technologies developed by aviation industry, several end-user motion chairs, predominantly intended for use in VE entertainment applications, became available in 1990s (Youngblut et al. 1996). However, Link's design was a motion simulator which did not include any external visual scene. Early visual systems were based on actual physical models, or pictures, such as the German bombers were trained in WWII, in which a continuous picture of a ground scene was rolled under the trainee who looked through the sight from a similar position to that in the actual bomber. Later, a miniature model of a scene around an airport was used over which a video camera traveled based on the aircraft's position as calculated by the flight model (Lawn 1998). The first computer image generation systems for flight simulation is developed for space program (Rolfe and Staples 1988). A version that is commercially available for civil aviation companies, Vital (Virtual Image Takeoff and Landing) was developed in 1969 as a laboratory prototype. The next version, Vital II, was approved by FAA and installed on a 737 simulator in 1972. Vital devices were only capable of visualizing lightpoints (Warwick 1987). Trainees see a night-like view of the landing scene at simulator's front windows, through a pair of cathode ray tube monitors. The VCASS (Visually Coupled Airborne Systems Simulator) was also an advanced flight simulator training of fighter pilots (U.S. Congress, Office of Technology Assessment 1994). Trainees wore a HMD that reflects the out of the window view. Thomas A. Furness, who worked as a scientist in the Wright-Patterson Air Force Base in 1970s, states that their efforts were also concentrated on design of virtual cockpits with very wide field of vision. In September 1981, their work lead to a virtual cockpit system with 120° of view on the horizontal (Carlson 2017).

Input Devices: Data Gloves, 6DOF Input, and Locomotion Systems

In 1976, Thomas DeFanti and Daniel Sandin developed an inexpensive, lightweight glove to monitor hand movements. Based on an idea of their colleague in Electronic Visualization Laboratory, Richard Sayre, the glow is named as Sayre Glove. Later in early 1980, MIT Architecture Machine Group used a camera-based LED system to track body and limb position for real-time computer graphics animation, termed "scripting-by-enactment." The method was intended as a body motion tracking system, which can be also employed for hand tracking. In 1983, Gary Grimes designed a glove, a specially tailored cloth for data entry using alphabet of hand signs with numerous touch, bend, and inertial sensors sewn on the glove. In 1987, the team of Thomas Zimmerman developed the Data Glove that uses fiber-optic wires and magnetic position tracking. Commercialization of the product led to a widespread use in research organizations, and inspired a commercial gaming glove that is manufactured in 1989 (Sturman and Zeltzer 1994).

As an alternative to relatively expensive gloves, 6DOF (six degrees of freedom) input devices were developed. In 1983, John Hilton sets out to develop a "3D force sensing joystick" for computer aided design applications while at the University of Sydney, Australia, and developed first prototype of Spaceball, which would lead to a line of products named as spacemice (spacemice.org 2016). Spacemice devices have a puck or ball that can be moved along X, Y, and Z axis as well as being twisted rotationally on each of those axis to roll, pitch, and yaw the 3D objects. An alternative input device type is flying mouse, or bat, originally developed by Ware and Jessome (1988).

Another type of input devices are locomotion interfaces that allow users to walk in the virtual environment. These type of interfaces appeared as

treadmills, sliding shoes, and foot pads, as well as some efforts to simulate walking with use of robotic tiles (Iwata 2013).

An early example of sliding shoes approach is Iwata's "harness and roller skate" design in 1989, in which the walker is fixed to the framework of the system by a harness and a pair of roller skate equipped with four casters which enables two-dimensional motion as the motion of the feet was detected by an ultrasonic range detector. The system evolved into "Virtual Perambulator," which employs touch sensor equipped rubber sandals with low friction film located at the middle of the sole (Iwata and Fuji 1996). Slater et al. (1995) used a method that does not require an additional hardware, by employing a neural network algorithm for analysis of the stream of coordinates from the HMD, to determine whether or not the participant is walking on the spot.

One of the antecedent locomotion treadmills were designed by James Lipscomb for the Walkthrough Project (Brooks 1987) in 1986, which uses a nonmotorized treadmill and bicycle handles. Since directionality is acquired through bicycle handles, the system was not an omni-directional treadmill. Within US Army Dismounted Infantry Training Program which began in 1992 (Singer et al. 1998; Knerr 2000), a unicycle-like pedaling system was developed in 1994, called Uniport. Uniport is the earliest example of foot pad approach in virtual locomotion, followed by the OSIRIS in 1995, which utilizes a stair stepper device as same as that used in athletic gyms. Uniport is replaced with Treadport in 1995, which is based on a unidirectional treadmill. Darken et al.'s (1997) omni-directional treadmill is a more advanced system, employing two layers of belts controlled by servo motors. The top belt comprised of an array of freely rotating rollers lies atop a second, orthogonally oriented belt also comprised of rollers. A tracking arm detects user's position. Another device within the treadmill approach, Virtusphere, utilizes a human-sized hamster ball. Built in 2006, Virtusphere is a ten-foot hollow sphere, which is placed on a special platform that allows the sphere to rotate freely in any direction according to the user's steps. User is able to walk and run inside the sphere, viewing the virtual environment through the head-mounted display (Medina et al. 2008). Circulafloor (Iwata et al. 2005) simulates an infinite surface by the circulation of a set of omnidirectional movable tiles. Each computer controlled tile move in the opposite direction of the walker's measured direction, canceling the motion of the step and fixing the walker's position. Currently, the locomotion devices have not become an affordable consumer product but there are several companies providing turn-key solutions for industry, academia, and business.

Mirror Worlds

Mirror worlds or projected realities provide a second-person experience in which the viewer is represented by her image taken by a video camera and merged into the virtual environment, and the computer processes the users' images to extract features such as their positions, movements, or the number of fingers raised (McLellan 2004). Computer artist Myron Krueger's efforts in combining interactive arts with VR were started in 1969, and led to Videoplace system in 1974 which is the earliest example of mirror worlds. The system employs video-based motion tracking to analyze the relationship between the user's image and the computer-generated objects and combines both on a projection display (Krueger and Wilson 1985). It can be used as a telepresence artifact for two users interacting with each other through the computer generated graphics.

Another early mirror world system dated back to 1986 is the Mandala VR System developed by a group of Canadian performance artists and commercialized as a product. The system employs a video camera that implements the captured video of the user into a computer generated environment or a previously taken video that is controlled by computer. There were several applications of the system including games and educational museum interactions (Wyshynski and Vincent 1993).

Virtual Projection and Virtual Spaces

In 1992, a research group in Electronic Visualization Laboratory and the School of Art and Design at the University of Illinois at Chicago introduced the concept of a room whose walls, ceiling, and

floor surround a viewer with projected images. The system they built had four screens, three walls, and a floor. It was named as CAVE (CAVE Automatic Virtual Environment), with a recursive acronym, in reminiscent of Plato's allegory of the cave (Cruz-Neira et al. 1992). Several CAVE systems were built around the world, mostly in research institutions to be used as a virtual environment, a virtual prototyping platform, and for visualizing scientific 3D spatial datasets.

Some examples are the CAVE's in Ars Electronica Center in Linz, Austria, which was the first to be installed outside the USA in 1996 (Kuka et al. 2009) and the world's first six-screen CAVE in Center for Parallel Computers at the Royal Institute of Technology in Stockholm, built in 1998 (Ihrén and Frisch 1999).

The advantages of CAVE environments over HMD displays is that multiple users can see each other in the CAVE at the same time, wearing shutter glasses instead of heavy helmets. System usually runs on a cluster of networked computers. Computers generate a pair of images following each other, one for each eye of the user, synchronized with shutter glasses. As a result, images seen by the user is three dimensional, as the objects are floating in the room. CAVE systems employ a motion tracking technology to locate the user in the room, besides interaction devices such as data gloves, joysticks, or wands (Manjrekar et al. 2014).

Consumer VR

In 1990s, VR systems became commercialized for consumers in entertainment industry. A leading attempt was committed by Jonathan D. Waldern (1992). Some of these systems that aimed to be commercialized as consumer products could not progress the prototype stage and failed to reach consumers, while other were commercial failures due to the conflict in users' high expectations and device's functionality and reality (Garner 2018). According to Stone (2008) "commercial naivety on the part of VR companies, significant failures to deliver meaningful and usable intellectual property on the part of so called academic 'centers of excellence,' expensive and unreliable hardware, an absence of case studies with cost-benefit analyses and a widespread absence of attention to the requirements and limitations of the end users" were factors that affected the development consumer level VR systems.

The first decade of the twenty-first century is described as the "VR winter" (Furness 2014). There was little mainstream media attention given to VR from 2000 to 2012, while there were no consumer level VR products. By 2012, ignited by a kickstarter project, companies ranging from start-ups to the Fortune 500 began to see the value of VR and started providing resources for VR development (Jerald 2015).

Definition

Holography as an architectural decoration is an application of holography to the everyday living space of a building.

Introduction

Applications of holography have been developed and implemented in many fields; display holography is the most important and exciting application (Ishii 2006b). Various types of holograms exist, each of which has its own unique color or luster characteristics; some examples are reflection, laser transmission, white light transmission (rainbow), silver halide, and dichromate gelatin (DCG) holograms. In particular, the DCG reflection hologram exhibits certain favorable characteristics such as a metallic luster or pearl color. The white light transmission (rainbow) hologram is particularly impressive because of the way it displays the colors of the light (Ishii and Tsujiuchi 2008).

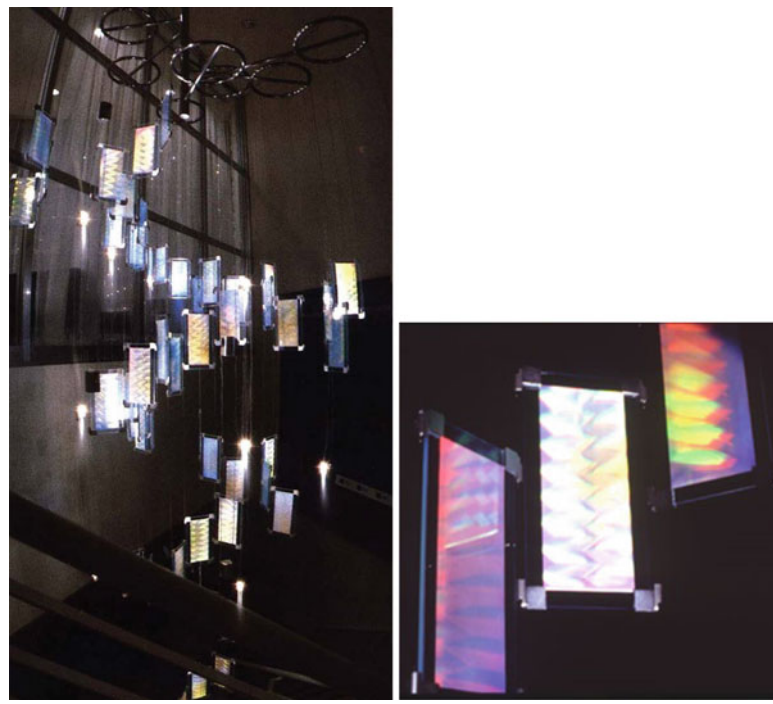
Various methods exist in which holograms are used as raw materials. Holograms are used in sculptural decorations as three-dimensional objects, atrium decorations, holography chandeliers, wall decorations, and in the staging of indoor prismatic displays of sunlight using holography grating.

This entry describes various attempts to bring the attractive, decorative applications of display holography into architectural spaces (Ishii 2007).

Shaw Cases

Holography Chandeliers

The work (Fig. 1) was installed in the stairwell of a pavilion building at the Science Exposition, which was held in 1985 in Japan. DCG holograms and low-voltage miniature halogen lamps were assembled together, which formed a holography chandelier.



Holography as an Architectural Decoration, Fig. 1 DCG reflection type of hologram

Sculptural Object

The case (Fig. 2) is installed in an entrance and consists of multiple DCG holograms, stainless steel poles, and a black granite base. Around the object's circumference, beams of light which are transmitted and/or are reflected from the hologram intersect. The use of the hologram in the design of the space has a significant influence on the surrounding environment. Its influence is especially noticeable at night when passing pedestrians can enjoy the object's brilliant effect in the entrance of the office building.

Holography as an Architectural Decoration, Fig. 2 Sculptural object in an entrance, 270 cm × 200 cm

Atrium Decoration in Public Space

Multiple DCG holograms and 10 large dichroic mirrors were combined and installed in a skylight window in 1997 at the public Health and Welfare Center of Japan. This demonstrates the combination of vivid color interference and holographic image (Ishii 2007). The appearance of the holograms and colors change constantly, depending on variance of ambient lighting conditions which is caused by factors such as weather and time (Fig. 3).

Wall Decoration

The works (Figs. 4 and 5) were finished in the shape of a mural painting. A silver halide reflection hologram with a diameter of 160 cm (Fig. 6) is installed in the basement (Ishii 1993). The reconstruction of the holographic image is enabled by guiding sunlight through optical fibers that stretch from the roof of the building to the basement (Ishii 2006a). Staff in the building are

Holography as an Architectural Decoration, Fig. 8 At a cafeteria

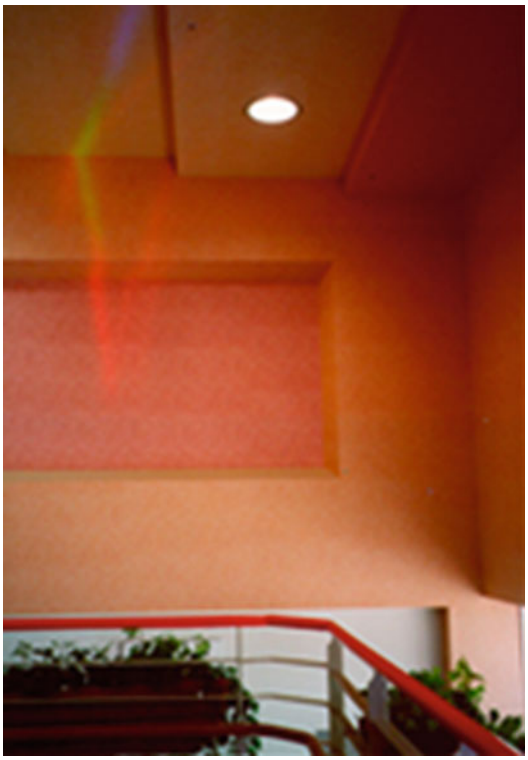
aware of the weather outside without moving from their seat.

Rainbow Production

When sunlight hits the grating installed in the crosspiece of a glass window, the diffracted light produces a rainbow color on a ceiling or wall (Figs. 7, 8, and 9). The rainbow moves across various surfaces with the movement of the sun. The sunlight's production of the rainbow carries brightness and peacefulness into an everyday living space. Holography is the easiest way to bring light of the sun inside a space (Ishii 2007).

Application for Large Format Multicolor Rainbow Holograms

Three large format multicolor rainbow holograms (Fig. 10b) were installed in a large-scale construction space (Fig. 10a) in 2003. Film holograms are laminated between two pieces of glass. Behind the holograms, a flat vessel containing water and with mirrors on its bottom is situated on the floor. The device produces ripples on the surface of the water that causes water droplets to fall from the top. The lights used for hologram reconstruction reflect from the mirrors under the water, adding dynamic movement and imparting a sense of vividness to the virtual image.

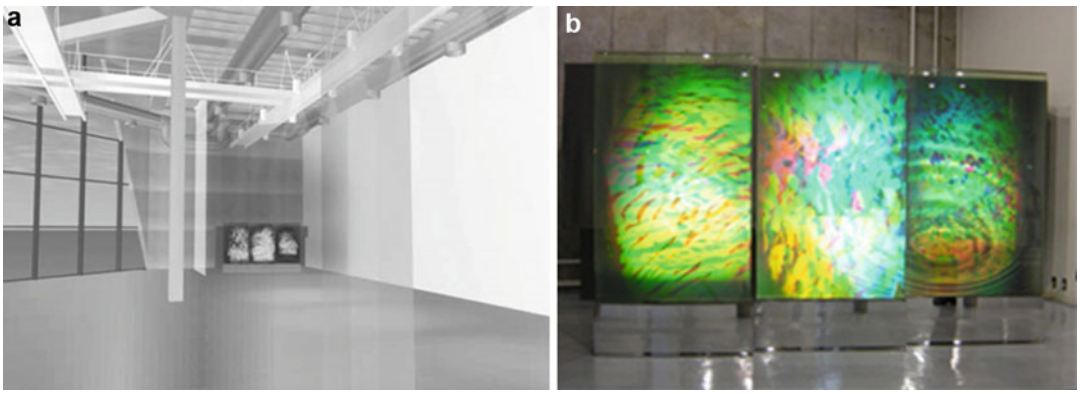


Holography as an Architectural Decoration, Fig. 9 Dining room of a care home for the elderly

The transmission hologram requires a large area behind the hologram for lighting. At this point, the type of reflection is easier to manipulate than the type of transmission. In the following cases (Fig. 11a–c), multicolor rainbow holograms were installed and are dependent on the quality of their reflection, which is produced by mirrors. The works in Fig. 11b, c are installed in Taiwan.

Conclusion

When a hologram is likened to a painting, a tile, or a pottery plate, it can hold great potential as a new material for wall surface ornamentation. The wonderful and attractive effect created by the holograms cannot be realized with any other materials currently used in everyday living



Holography as an Architectural Decoration, Fig. 10 (**a**) At Tokyo Institute of Technology. (**b**) Multicolor transmission hologram with water ripple, 210 cm(h) × 300 cm(w) × 250 cm(d)

space. When a space is designed to accommodate the use of a hologram, it has a significant influence on its surrounding environment and produces brilliant, delightful, and comfortable spaces.

Definition

The use of illuminated light waves to create three-dimensional photographic representations of objects. Typically recorded on a photographic plate or film with a pattern of interference formed by split laser beams that scatter light and create the appearance of a three-dimensional shape once interacted with by light.

Introduction

The history of holographic technology begins hundreds of years ago in the inspiration of the past. Carried forward to each generation by strategic people, the total history of holographics is challenging to capture concisely. Below is an account of important people, pivotal moments, and critical inventions that brought us to our holographic technology of today.

History of Holographics

Holographics has a forebearer in the concept of "Pepper's Ghost." Inspired by the 1584 research of Italian scientist Giambattista della Porta, the inventor of the camera obscura, Henry Dircks experimented with bouncing images off of plate glass and created Dircksian Phantasmagoria, which he presented to the Association for the Advancement of Science in 1858 (Howard 2015). Dircks tried to sell his effect to theaters, but with no luck. It was a few years later in 1862 that John Henry Pepper modified the setup and projected ghosts for Dickens' *The Haunted Man*, and while he tried to give proper credit to Dircksian, it became renowned as "Pepper's Ghost." This would turn up at fairgrounds, haunted houses, magic shows, and any venue seeking to add flair until the technology modernized (Howard 2015).

Holography is a now familiar technology from its once obscure background. Derived from the Greek words holos, meaning "whole," and graphe, meaning "something written," it was coined in 1947 by British scientist Dennis Gabor while working on improving the resolution of an electron microscope. After learning of Gabriel Lippmann's work at the young age of 15, Gabor became inspired to study physics. Lippmann developed a theory of using light interference to capture color photography decades prior in 1886, eventually creating perfect color photographs to the Academy of Sciences in 1893 and publishing his full theory in 1894. He won a Nobel Prize for his work in 1908 and later became an adviser at the Physics Department at the Sorbonne, where he introduced Marie Sklodowska to her future partner and scientific genius Pierre Curie (History of Holography 2016).

Learning of this research, Dennis Gabor became inspired. But his story comes from a time of strife. He, as Lippmann, was also Jewish. He relocated to England to escape religious persecution at the hands of the Nazis in 1933 (History of Holography 2016). It was then that he moved to Thomson-Houston Research Laboratories in Britain. It was during his stay there that he developed the theory of holography, but due to technical infeasibility of the concept at the time, it would be another 20 years before the technology that we know as holography was able to come to fruition. He was attempting to improve the resolution of the electron microscope to be capable of seeing singular atoms, but came upon his own theory of wavefront reconstruction, soon to be called holography. What was required would be a powerful form of

light, which came in the 1960s with the invention of the laser. This allowed for the intense, coherent light necessary to construct holograms.

Holographics represents another trend for humanity, our ability for many of us to stumble upon a similar technology at the same time. While not knowing of Gabor's work, a Russian in the former Soviet Union by the name of Yuri Denisyuk became inspired by the very man that inspired Dennis Gabor, Gabriel Lippmann. After reading of Lippmann's work, he began to experiment in 1958 using a highly filtered mercury discharge tube, as there were no lasers yet. His work was published in 1962 to lackluster support. It wasn't until a visiting delegation of American scientist requested to meet with him that he saw his own esteem and fortunes rise.

Emmett Leith is another individual that followed a similar hunch like Gabor and Denisyuk. At the relatively young age of 25, he began researching highly classified works at the University of Michigan's Willow Run Laboratories in 1952. He was set to work to study synthetic-aperture radar (SAR). The army desired high-quality imaging radar system, but without further innovation in the field, then the antenna was projected to be so large that no airplane could carry it. They sought to create a synthetic antenna that had high-powered capability because it processed image data like a hologram – within small pieces over transmitted pulses. By 1957, Leith's new method was ready to be tested. After eight flights yielded no images, the critics seemed validated in their doubts of such a technology; however, on the ninth flight, the terrain was beautifully captured and the SAR system became famous (Emmett Leith).

It was in the 1960s that Leith turned toward the work of Dennis Gabor, realizing that there was more interesting research to be conducted. Gabor's work produced fuzzy images that also contained twin images, and the doubling of images was deemed unsolvable. Leith approached Juris Upatnieks, whom was not originally impressed by the work and recently joined the facility but become convinced after reading Gabor's experiment in *Principles of Optics* by Born and Wolf (1959).

Upatnieks had fled the Soviet occupation of Latvia with his parents, seeking asylum in Germany, and eventually emigrating to the United States (Emmet Leith and Juris Upatnieks Co-Inventors of Holography). He attended high school in Ohio, and after studying Electrical Engineering at the University of Akron, he received his Bachelor's degree in 1960 and began conducting research at the Michigan facility. What this pair would create together would cement their hands in the creation of modernized holographics, as they solved the twin image issue and greatly improved the technology. Even Gabor himself would mention Leith and Upatnieks in his 1971 Nobel Prize speech, stating that their success "was due not only to the laser, but to the long theoretical preparation of Emmett Leith, which started in 1955. . . This was in fact two-dimensional holography with electro-magnetic waves. . . Their results were brilliant" (Emmett Leith).

Like other technologies, the 1960s and 1970s were a time of true maturation. In 1965, Robert Powell and Karl Stetson published a paper on holographics interferometry, which proved useful for nondestructive testing of materials, fluid flow analysis, and quality control. Larry Siebert of the Conductron Corporation utilized a pulsed laser to create the first hologram of a person in 1967. This was instrumental in the early days of commercial display holography. Unfortunately, a recession in the early 1970s forced the company to close, shutting the door on a potentially huge market.

The late 1960s saw Stephen Benton's invention of white-light transmission holography while researching holographic television for Polaroid Research Development (Sergey). It was significant because it made the mass production of holograms possible by stamping the interference patterns onto plastic. These holograms could be duplicated millions of times over for a few cents apiece. This created embossed holograms that are now utilized by publishing, advertising, and many other industries.

Lloyd Cross combined white-light transmission holography with more conventional cinematography processes to create more realistic illusions. One of the most famous is a series of photographs called "Kiss II" in 1974, which was made from approximately 360 frames and shows

an image of a woman named Pam Brazier blowing a kiss and winking at the viewer as they walk by (History). He would later create Multiplex Company that produced hundreds of images using his technique.

The field of holography was divided into several camps. There were researches, artists, and artisans. In 1972, Tung Jeong began offering summer workshops for non-physicists at Lake Forest College in Illinois. This introduced a new medium for expression for artists that many ran with. Artists like Salvador Dali utilized holographic technology in exhibitions, such as at the Knoedler Gallery in New York. Work like his and others contributed toward the mainstreaming of this technology, as more of the public was introduced to it.

Through the next few decades until the millennia, there was the development and application of the technology across different spaces. The 1980s saw more integration of the technology to familiar items. In 1983, MasterCard International, Inc. was the first to use hologram technology in their banking security (History). It was deemed the largest distribution of holographic technology at that time. It was in March of 1984 that holographic technology made its way onto the cover of the National Geographic (volume 165, Number 3), with nearly 11 million holograms being carried throughout the world (History). In 1997, German inventor Uwe Maass created a roll up, transportable technology that enabled a new type of holographs that he deemed "eyeliner." This technique was modernized and utilized by a company called Zebra Imaging. The army utilized the technology in 2006 to have field maps that were 2 × 3 ft and could have a light shined on them which reveal a hologram of the terrain before them. It would show the steepness of the topography and where they might be vulnerable to ambush. The three- dimensional aspects of the new maps were a hit, and over 14,000 holographic maps were utilized by American troops in Iraq and Afghanistan over the next decade (Howard 2015).

Some might remember the 2005 concert where Tupac was presented on stage, while some may consider this a hologram technology, it was actually a twenty-first-century application of Pepper's Ghost. A custom-developed foil was utilized in the technique to create more realistic images. Tupac is not the only artist to be brought to life using this type of technology. The cartoon band by the name of the Gorillaz has long experimented with the concept, but due to technical issues, hologram-based concerts were still a challenge to tackle, and it took several more years before we were able to sit in a truly hologram-like experience.

In 2014, Uwe Maass came into the limelight again. Forming a venture with his peers, he created Hologram USA and MDH Musion, both of which are doing amazing things in the field of holographics. One example of the impressive sway this technology can hold comes from Narendra Modi, whom entered the race for Prime Minister of India. With low polling numbers, he hired MDH Musion and began delivering speeches simultaneously at hundreds of rallies across 1400 locations – reaching an estimated 14 million additional voters. His numbers went from a low 34% to 53% and won him the election (Howard 2015).

The 2016 live performance by Callie and Marie at Niconico Tokaigi, Japan (Splatoon 2016), and the 2018 Hatsune Miku Concert in Los Angeles (Hatsune Miku Concert 2018) have both demonstrated new advances in holography where concertgoers were able to enjoy a hologram-like experience.

The holography market is projected to hit $3.57 billion by 2020 (Holographic Display Market). With applications across entertainment, military operations, financial markets, politics, work, and home use, there is an appetite for the technology. After many decades it took to bring it to full actualization, the twenty-first-century evolution of the technology may finally bring what we have been only able to speculate in science fiction novels to life.

Human Interaction in Machine Learning (ML) for Healthcare

Sara Al Hajj Ibrahim and
Fatemeh Dehghani
Faculty of Science, Ontario Tech University, Oshawa, ON, Canada

Synonyms

Artificial intelligence; Deep learning; Machine learning; Neural networks

Definitions

The field of artificial intelligence (AI) is the development of machines that can perform human-like tasks, such as reasoning, perception, and decision-making. Machine learning (ML) is a subfield of AI that allows machines to learn from data without the need for explicit programming. Neural networks (NN) and deep learning (DL) take this a step further by enabling machines to learn from complex and unstructured data like speech, images, and natural language, and use that data to make predictions. NN is an ML algorithm that imitates the structure and function of the human brain, consisting of interconnected neurons that process information. DL is a specific subset of NN that utilizes multiple layers of artificial neurons to enable machines to learn and make predictions from vast amounts of data. Human-computer interaction (HCI) studies how people interact with digital technologies and designs interfaces and interactions that are user-friendly and intuitive. This is essential in creating effective and efficient AI and ML systems that enhance human-computer interactions. Together, these technologies and approaches work in harmony to create intelligent machines and improve the user experience.

What Is Machine Learning (ML)?

Machine learning (ML) is a type of artificial intelligence (AI) technologies that allows software applications to become more accurate at predicting outcomes. There are vast opportunities that ML gives, some being used right now, others yet to come. As ML becomes pervasive in our day-to-day applications, most systems nowadays involve ML. ML led to better outcomes and improved efficiency in most scenarios. In this context, systems implement and utilize different ML and AI algorithms. The nature of ML implementation involves systems having a more significant than a typical role in obtaining, utilizing, and protecting data. ML models extract valuable features and insights from data to detect different activities in systems. Systems are now responsible for more advanced and expensive decisions.

Machine Learning (ML) in Healthcare

Due to the improvement in ML, the variety of applications for healthcare information systems has increased dramatically. This advancement has opened the door to many medical operations based on ML models. ML systems provide medical situational insights, quick medical reminders, and accurate medical forecasts (Koh and Tan 2005). Utilizing these cutting-edge technologies has accelerated the digitization of healthcare institutions, primarily driven by the need to improve medical processes. ML systems are now a tool that can supplement physicians' decision-making process, generate individualized and customized health management plans, predict the next health crisis, and develop personalized treatments that employ precision medicine (Chancellor et al. 2016).

In recent years, healthcare systems got involved in many AI and ML contexts, from monitoring things such as diabetes (Nasser et al. 2021) and cancer care (Onasanya and Elshakankiri 2021; Pradhan and Chawla 2020) for identifying different kinds of pathologies and chest x-rays or even in mental health as identifying depression

(Kumar et al. 2021). Healthcare systems now can predict and control any new infectious disease, e.g., COVID-19 (Mukherjee et al. 2021) or Monkeypox (Ahsan et al. 2022). As such, ML and AI in healthcare have shown to be very extensive in achieving a higher quality of service and patient health.

Interactive ML (I-ML)

Real-world uses of ML techniques have shown weaknesses that result in poor results and the need for improvement. ML algorithms require access to good-quality, unbiased, and complete training data to work optimally. In most cases, a lack of high-quality data leads to poor results. While ML techniques can provide exact and quite well solutions for well-structured problems, they are unsuccessful for nondeterministic polynomial time (NP)-hard and ill-conditioned problems. Humans are the only entities capable of explaining the limitations of ML approaches since humans are excellent at abstract thoughts and solving computationally complex problems. As such, one way to improve the performance of ML systems is through human involvement in the process. The mechanism through which humans and ML systems work together is known as interactive machine learning (I-ML). It is feasible to construct systems more quickly and effectively by merging human feedback with ML, and that leads to more precise system design and predictions that are more accurate. For example, Fails and Olsen established I-ML, showing its importance and promise (Fails and Olsen 2003). Moreover, in (Zerilli et al. 2019), Zerilli et al. discuss including individuals in decision-making. Humans and ML will need to work together in the future for many ML applications, no matter how well planned. Elish and Watkins observe that using an AI system to assist in identifying sepsis patients disrupted clinical operations and drove nurses to devise novel solutions to the problem (Elish and Watkins 2020). Nurses are responsible for integrating AI findings with established clinical diagnostic procedures. In (Nascimento et al. 2018), ML experts attempt to automate streetlights using ML. In many cases, humans outperform AI. To improve the design of automated streetlights, a human–AI interface using both human and ML techniques is presented. In a different case, the text is put into groups using ML, even though the initial data processing was done automatically (Yang et al. 2019). Humans are added to the loop if the first results are not good enough. Such issues show some limitations of ML, and that human understanding is the primary remedy. ML can deliver precise and accurate solutions to well-structured queries, but not too ambiguous ones while building complex new algorithms. When humans and ML techniques are combined, systems become more effective and exceptional, as humans are the most informed and possess abstract thought.

I-ML in Healthcare

Various research on human behavior for Al interactions has been published in the field of medical applications. Protein structure, genomic annotation, image analysis, and knowledge base population are healthcare problems still requiring human involvement. In some instances, many humans are necessary; in others, we need only a limited number of highly trained professionals in specific fields. For example, in (Caruana et al. 2006), ML and biochemists work to categorize low-level protein structures. They begin by clustering protein structures. After then, biochemists would discuss the data. Biochemists review the discoveries and apply new constraints for the next iteration. Clustering parameters are next changed to fit restrictions. In another study, experiments evaluate the I-ML "human-in-the-loop" technique, especially when it comes to opening the "black box" and letting a person alter and interact with an algorithm directly or indirectly (Holzinger et al. 2016). The research involves a framework for the traveling salesman problem that solves practical difficulties in health informatics, such as protein analysis. In (Holzinger 2016), a study identifies a problem by finding globally optimal protein threading, which checks if threading with a score less than or equal to K exists. This problem is categorized as NP-hard. Problems labeled as

NP-hard cannot be solved in polynomial time. One of the primary advantages of human interaction in ML is the ability to tackle NP-hard problems. Another study in (Holzinger 2016) discusses the k-anonymization problem of a record publication that cannot be identified from k other entities in the data. While the task of k-anonymization is similarly NP-hard, the suppression or generalization of attributes can measure the effectiveness of the outcome until each database row is identical to at least k−1 other row. Using generalization and suppression, an extension of the k-anonymity model maps any given record in the dataset to at least k others. A human best performs this.

Experts Within Healthcare I-ML

In I-ML applications, when the task is professional and complicated, we observe that humans with a higher domain expertise should be in the loop. With the help of domain experts, ML applications have coined a new term: HILML, or human-in-the-loop machine learning (Maadi et al. 2021). Generally speaking, for humans who collaborate with ML methods, the more expertise is, the better human–ML interaction outputs are achieved. Their assistance entails incorporating patient-specific information, treatment outcomes, and any additional repercussions associated with previous decisions made by the semi-automated system. In addition to assisting with pattern recognition and providing data from the outside, their assistance also includes giving external data. It is very beneficial to combine the specialized knowledge of medical professionals, such as physicians, and doctors, into intelligent healthcare systems through interactive ML, which is later strengthened by further data and expert knowledge. According to (Budd et al. 2019), there are two stages where medical professionals can help.

– Training phase: The training phase consists of inputs and predicted output pairs manually labeled by experts. Expert engagement is helpful in assisting ML when datasets are small or of poor quality. Hence, medical experts add new annotations to be used for model training. Moreover, experts fine-tune the model using the new recent annotated data until the ML algorithm is optimal. In the discipline of ML, "annotation" refers to labeling data to indicate the outcome you want the model to predict. In this context, we train a model with the new annotations, and the model then uses the latest data to increase its prediction accuracy. As such, we acquire more precise labels. This procedure, where experts feed data to the computer to assist future decisions, is known as supervised ML. The goal of training is to enable the algorithm to make correct decisions when presented with new data. Unlabeled datasets, on the other hand, are employed as unsupervised ML. Under these conditions, the algorithm is programmed to seek and define its own structure of unlabeled data. This part is referred to as a deep learning (DL) approach.

– Testing phase: Testing and evaluation from experts help in fixing wrong results. There are two kinds of wrong decisions: those in which the algorithm is uncertain and those in which the algorithm is certain, but the outcome is incorrect. To solve this problem, and after an ML model has been trained, experts evaluate model predictions and make changes to it to get the most accurate results for data. When experts are involved, automated predictions may need to be changed by hand in order to meet those criteria. A model must be capable of communicating with experts to provide meaningful interpretations of model predictions. This lets users take the best action when interacting with model outputs and decreases human uncertainty.

I-ML and Serious Games

Serious games are becoming increasingly important in the field of I-ML in healthcare as they offer a unique and efficient way to solve medical problems. By simulating real-world medical scenarios through games, medical professionals can assess their decision-making skills and improve their ability to diagnose and treat patients in a controlled and safe environment. I-ML uses serious games to provide healthcare professionals with

hands-on learning opportunities and the opportunity to apply their knowledge in a hands-on environment. In (Wang et al. 2016), a systematic review aims to assess the current state of research on the use of serious games in healthcare and provide an overview of such games' history and current usage. The authors further discuss potential benefits and challenges associated with using serious games in healthcare.

I-ML also uses computer graphics and data visualization to create virtual environments that enable medical professionals to visualize and interact with complex medical structures and processes. Additionally, serious games can provide real-time feedback and analytics by monitoring player performance. This allows you to identify and address improvements. This kind of feedback is extremely valuable to healthcare professionals as it supports ongoing skill development. A study explores the role of visual analytics in healthcare and provides a comprehensive overview of state of the art in the field (Preim and Lawonn 2020). It also covers various topics, including visualization techniques, interactive graphics, data-driven models, and decision support systems.

Games are a valuable tool in health education and can be used to educate patients about their health, provide tools for effective health management, and guide better health outcomes. They can be used for patient education, physician training, and medical scenario simulation. The benefits of using serious games in healthcare include improved knowledge retention, engagement, and decision-making (Cain and Piascik 2015). It has also been shown that it can educate patients about and improve health outcomes in the management of chronic diseases such as diabetes (Talley et al. 2019).

Prons and Cons of I-ML on Healthcare

In healthcare systems and society, the most critical tasks for I-ML are fostering trust and transparency. I-ML provides patients, clinics, hospitals, specialists, and everyone interested with transparency in its services. It is imperative that patients establish reliable connections with ML systems. For example, if a patient is told that an image led to a cancer diagnosis, they will undoubtedly want to know why. Moreover, ML systems can deliver more accurate assessments combined with the expert knowledge of healthcare professionals, particularly when using small or poor-quality healthcare datasets. This is done using the previous two roles mentioned, data labeling combined with consistent feedback on the algorithm's decisions.

On the downside, however, experts need to frequently annotate data during the learning phase and verify the decisions suggested by the ML model to ensure that it is the best decision regarding the risks imposed on patients. The process of data labeling and continuous feedback are time-consuming manual processes. Labeling requires experts to annotate and categorize complex images such as X-rays, CT scans, etc. Also, whenever experts are added, the cost of bringing doctors or other experts into the loop makes it costly. Nevertheless, if there were errors, it would result in a considerable increase in the cost. In practice, and to save costs, it is feasible to determine what confidence level is acceptable for the ML models involved. Confidence criteria can be lowered if wrong decisions do not have a negative impact, requiring less expert engagement and lowering the cost of interactive ML.

Discussion and Conclusion

Few studies have been completed on AI and human collaboration in healthcare, and new research is being conducted in this field (Bossen and Pine 2022). This indicates that there are still important considerations when attempting to incorporate ML into everyday life. More research is required to identify the when, where, and why of collaboration between humans and ML in healthcare systems. Together, ML and humans in healthcare may be incapable of making the best decisions. It has been proved that when ML incorporates information from various sources, it can surpass humans in decision-making in some scenarios (Liu et al. 2019). In addition, most studies evaluating ML's application in healthcare have

focused on improving the accuracy of medical workflows. ML is anticipated to impact healthcare administration as well drastically (Bossen and Pine 2022). Given the recognized limitations of both human reasoning and ML, it is still being determined whether doctors and ML systems can rely entirely on one another to make accurate decisions.

Researchers believe that human connection is essential for ML to succeed in gaining expert confidence in a healthcare context. To put this in perspective, most researchers do not come from a medical background, in striking contrast to medical practitioners. Interactions with medical professionals, whom each have their distinctive blend of knowledge, experience, and expertise, have the potential to improve ML systems. Following an analysis of the relevant research, combining ML with human input has the potential to enhance the delivery of healthcare. This entry highlights the potential reliability and precision of decisions generated by ML algorithms supported by the knowledge of medical experts.

Hypermedia Narrative as a Tool for Serious Games

Andrés Adolfo Navarro-Newball[1],
Borja Barinaga López[2] and
Isidro Moreno Sánchez[3]
[1]Electronics and Computer Science, Pontificia Universidad Javeriana, Cali, Colombia
[2]Universidad Francisco de Vitoria de Madrid, Madrid, Spain
[3]Universidad Complutense de Madrid, Madrid, Spain

Synonyms

Interactive digital literature; Interactive multimedia narrative; (as a tool for) Applied game; Formative game; Game with a purpose; Games for change

Definition

Hypermedia refers to interactive multimedia in a nonlinear medium. It may include video, plain text, audio, graphics, and animation brought together using hyperlinks (links referring to data). A narrative is a story or report connecting events. It may include characters, time (duration and frequency), and a space where characters develop and perform actions. Hypermedia narrative is a tool to develop ideas, documents, and multimedia using digital tools.

A game is an activity with specific rules related to a physical or mental feeling of evasion of reality and enjoyment performed by one or several players who freely participate to solve a challenge. A video game is an interactive computer-based game using a user interface to provide feedback, which includes automatic processes and actions and hidden rules occurring in the computer. A serious game is a sort of game software developed with intentions going beyond entertainment. Games may integrate a story, game mechanics (rules of the game) and dynamics, technology, and arts (visuals and sound) to create a playability.

Hypermedia narrative as a tool for serious games refers to using it to impact the story of a game, affecting its mechanics and arts thorough the use of interactive technology to produce nonlinear playability. The idea is motivating emotions and using interactivity to make the player live those emotions with a purpose that goes beyond mere entertainment.

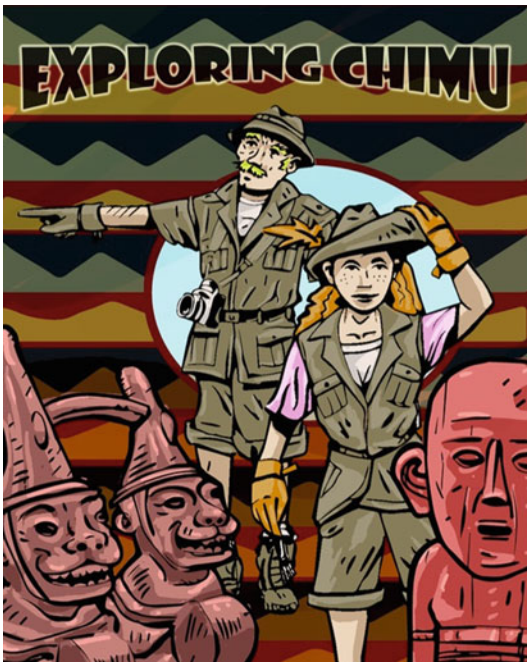
Introduction

Games favor knowledge acquisition and retention and force players to focus on solving problems. Their use brings benefits such as engagement, motivation, skills development, and learning. Serious games have been widely used and have gained the attention of researchers because they can capture players' enthusiasm while raising awareness of diverse subjects (Prakash and Rao 2015).

Hypermedia narrative allows the author and the reader to approach the creative process of a new story promoting a partnership which empowers the reader as a reader-author. Within this process, interactive stories, such as the ones used in games, are deconstructed and built again, while the meaning attributed to them and the degree of implication of the reader-authors are in continuous change. Space, time, personages, and actions conform the contents used by authors and reader-authors to construct an interactive speech (Prakash and Rao 2015).

Example

Hypermedia narrative can be used in contexts such as museography (museum methods of classification and display). The Exploring Chimú exhibit at the Museo de América in Madrid, Spain, was developed in four phases (Prakash and Rao 2015). The result was Exploring Chimú (Fig. 1), a serious game where the player is an archaeologist who finds a Chimú pyramid (the



Hypermedia Narrative as a Tool for Serious Games, Fig. 1 Exploring Chimú's promo

Tantalluc pyramid) in the ancient Peru (Navarro-Newball et al. 2016). The Chimú culture inhabited Northern Peru between 1000 and 1470 (Navarro-Newball et al. 2016).

Phase 1: Writing the Narrative Script

Hypermedia narrative was used to identify, analyze, and validate important visual and textual elements, points of nonlinear interaction, and potential technological solutions. An interdisciplinary team of artists, information scientists, archaeologists, designers, cultural managers, and computer scientists reunited to build a narrative script. Cultural managers coordinated the interaction among professionals. Archaeologists made sure that the script had historical rigor. Artists created 3D visual models for the script and 2D models for the user interface. Designers proposed the layout of the exhibit. Information scientists identified potential points of interaction within the narrative. Computer scientists validated the technical feasibility of the proposal. The interdisciplinary team served the interactive storyline in a way that the player (reader-author) feels the contents as his or her own (as coauthoring this story).

Phase 2: Developing the Interactive System

Hypermedia narrative was used to validate the user experience and the archaeological rigor of the prototypes iteratively provided by the developers. The team found that user interaction had to be simplified. Artists developed 3D and 2D models to be used in the video game, and computer scientists programmed it. The rest of the team and likely users helped in the continuous validation of the interactivity provided by a gesture sensor and the interactions performed by the players to achieve a good user experience model.

Phase 3: Production

Hypermedia narrative was used to validate the original narrative script developed in the first phase against the resulting serious game. It was an opportunity to perform the final user experience validation and to test the game's accessibility. The team found that the system lacked some audio output and that the sensor had to be adjusted to support people of different heights. This phase was oriented by the information and computer scientists.

Phase 4: Final Implementation

Hypermedia narrative was used to integrate the serious game within the museum environment coherently. The designer developed a layout including actual archaeological pieces related to the pieces shown within the game, thus, integrating the museum's real experience with the virtual one. The rest of the team validated the implementation.

Trends

Mobile technologies can provide portability that goes beyond the place where the actual interactive serious game has been deployed. Artificial intelligence can provide automated interactions, behaviors, contents, and evaluations adapted to the user or the context where the system is deployed. Mixed and virtual realities can provide usable and novel immersive interfaces that augment contents. Technology usage guided by hypermedia narrative supports the development of better and more immersive interactive storylines, augmenting knowledge and making it accessible in a noninvasive manner (Moreno Sánchez and Navarro Newball 2016).

For example, Towards Tantalluc (Prakash and Rao 2015) is a mobile application where the player is a Chimú native who builds the objects that are going to be taken to the Tantalluc pyramid. Once an object is built, the player must find it in the museum collection and have an augmented reality experience with it, using a mobile device. In this case, what mobile and mixed reality technologies do is to motivate the visitor to walk and observe the museum exhibit.

Conclusion

With hypermedia narrative, an interdisciplinary team where members must contribute in all phases

of the process actively considers technological trends and advances coherently to develop serious games creating interactive storylines that augment knowledge and make it accessible. Hypermedia narrative usage in an educational game for a museum was shown. It can be used in other kinds of serious games such as speech therapy games (Navarro-Newball et al. 2014) and environmental consciousness (Prakash and Rao 2015), among others.

Introduction

Hologram can record and reconstruct or playback an optical wavefront on the hologram plane. It uses interference between two waves, an object wave from the object to be recorded and a reference wave. The interference intensity pattern is recorded on a photosensitive material. Computer-generated hologram (CGH) simulates this optical phenomenon in a computer (Lohmann and Paris 1967). CGH is widely used to show not only for 2D images but also complex 3D images. Image quality of the reconstructed image from CGH is usually evaluated subjectively. For example, an observer compares two images and scores. Here shows basic research to evaluate reconstructed image quality of phase-type CGH objectively on its peak signal-to-noise ration and brightness (Yoshikawa and Yamaguchi 2015).

Computer-Generated Hologram

The Fourier hologram can be calculated with the Fourier transform of an original image. Figure 1a shows the image location in the input image plane for the Fourier transform, and Fig. 1b is a synthesized CGH. Figure 1c shows a numerically reconstructed image from the CGH. As one can see from Fig. 1c, the reconstructed image includes the desired image appeared as same position of the original image and the conjugate image that appears as the point symmetry to the center. The direct light (or non-diffracted light) is eliminated numerically in the figure, but it usually appears at the center and should be taken into account to evaluate image quality. The original image should be placed off-center not to overlap with the direct light and the conjugate image. Therefore, the original image is located center in vertical and right most side in horizontal. For the hologram calculation, the pixel value other than the original 2D image is set to zero. The random phase is multiplied to each pixel to make the reconstructed image diffusing and bright. Then 2D Fourier transform is applied to the transmittance distribution of $o(x, y)$ on the input image plane, and the result of $O(X,Y)$ represents the complex amplitude of the object beam on the hologram plane. If the reference beam is collimated and its direction is perpendicular to the hologram, the complex amplitude of the reference beam $R(X,Y)$ can be represented as the real-valued constant r. The total complex amplitude on the hologram plane is the interference of the object and reference beam, represented as $O(X,Y) + r$. The total intensity pattern

(a) 2D image location on an input image plane.

(b) Calculated CGH.

(c) A simulated reconstruction image from the Fourier hologram.

Image Quality Evaluation of a Computer-Generated Phase Hologram, Fig. 1 Image location and reconstructed image of the Fourier transform hologram. 2D image size $W = H = 120$ and the hologram size $N = 256$

$$I(X,Y) = |O(X,Y) + r|^2 = |O(X,Y)|^2 + r^2 + rO(X,Y) + rO^*(X,Y) = |O(X,Y)|^2 + r^2 + 2r\Re\{O(X,Y)\}, \quad (1)$$

is a real physical light distribution on the hologram, where $\Re\{C\}$ takes the real part of the complex number C and $C*$ means the conjugate of C. At the right most hand of the Eq. 1, the first term represents the object self-interference, and the second is the reference beam intensity. The third term is the interference of the object and the reference beams and contains holographic information.

Calculation Without the Object Self-Interference

In the CGH, it is quite easy to use only the interference term $2r\Re\{O(X,Y)\}$ of Eq. 1. This idea is proposed at very early stage of CGH research (Waters 1966). The interference part can be written as:

$$I_b(X,Y) = \Re\{O(X,Y)\}. \quad (2)$$

The normalization defined in Eq. 3 is applied to make final fringe intensity positive,

$$I_n(X,Y) = \frac{I_b(X,Y) - I_{\min}}{I_{\max} - I_{\min}}, \quad (3)$$

where $I_{\max}$ and $I_{\min}$ are the maximum and the minimum values of $I_b(X,Y)$, respectively.

Numerical Reconstruction of Phase Hologram

For reconstruction simulation, the complex amplitude transmittance $t(X,Y)$ of the transmission phase CGH is assumed as:

$$t(X,Y) = \exp[-i\Delta\phi I_n(X,Y)]. \quad (4)$$

Then $t(X,Y)$ is inverse Fourier transformed to obtain the reconstructed image. In the case of a sine-wave phase grating, the maximum diffraction efficiency of 33.8% is obtained at $\Delta\varphi = 0.59$. Therefore, this value is used unless denoted.

Diffraction Efficiency

The diffraction efficiency (DE) is defined as the ratio of the intensities of the reconstructed image and the illumination light. It gives the brightness of the reconstructed image. In the numerical experiments, the reconstructed image intensity is obtained by summing up all intensities in the reconstructed image area as same size and position of the original image in the input image plane.

Peak Signal-to-Noise Ratio

The peak signal-to-noise ratio (PSNR) is defined as the ratio of the maximum signal power and the noise power. The reconstructed image is extracted from numerically reconstructed image plane such as Fig. 1c and normalized to 8-bit grayscale image that has same mean intensity of the original image, and then the PSNR is calculated as:

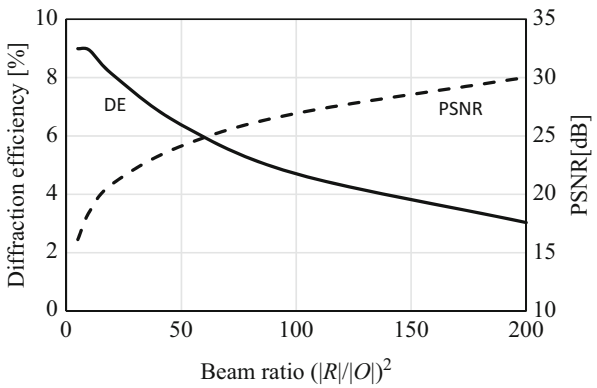

Image Quality Evaluation of a Computer-Generated Phase Hologram, Fig. 2 Diffraction efficiency and PSNR against beam ratio for transmission phase hologram. Solid lines show DE, and dashed lines show PSNR

$$\mathrm{PSNR} = 10\log_{10}\frac{255^2 WH}{\sum_{i=0}^{W-1}\sum_{j=0}^{H-1}[J(i,j)-K(i,j)]^2}\,[\mathrm{dB}], \tag{5}$$

where W and H are horizontal and vertical pixel numbers of the image and J and K are intensities of the original and the reconstructed image.

Numerical Experimental Results

Figure 2 shows DE (solid line) and PSNR (dashed line) of the rigorous calculation against the beam ratio (BR, defined as $|R|^2/|O|^2$). The DE of the phase hologram becomes over ten times larger than that of the amplitude hologram (Yoshikawa 2015). Since the object self-interference (OSI) term of $|O|$ in Eq. 1 causes noise on the reconstructed image, it is known that larger beam ratio gives better PSNR. However, DE becomes smaller with larger beam ratio. The hologram calculated without OSI as shown in Eq. 3 gives PSNR of 25.0 dB with DE of 8.8%, which achieves both low noise and bright image simultaneously.

Conclusion and Discussion

Image quality of phase CGH is evaluated objectively on the diffraction efficiency and the peak signal-to-noise ratio. For the transmission phase hologram, although it is obtained over ten times of diffraction efficiency against amplitude hologram (DE = 0.77%, PSNR = 38.9 dB), PSNR is not as good as that of the amplitude hologram. Since the evaluated hologram is very simple phase hologram, it is expected to evaluate other type of phase hologram.

Computer-aided design (CAD); Computer-aided industrial design (CAID); Three/Two dimensional (3D/2D) graphics; Virtual pottery (VP); Virtual/Augmented reality (VR/AR)

Definition

Imagineering in Virtual Pottery is to realize the artist's dream of creating intricate shapes.

Imagineering at the next level seeks realistic interaction with the shape digitally using devices that provide the touch and feel of real pottery in the virtual world. To push the boundary further in imagineering, the artist wants the virtual clay to be malleable and behave like real clay in capturing intricate shapes, and also it is printable. Ideally, imagineering in virtual pottery enables and demands bidirectional fluidity.

Introduction

Traditional pottery relies on the hand skills of an artist, the ceramic material and an understanding of the kiln and making process. This is further refined by a range of decorating, glazing, and firing techniques. The artist also uses techniques such as hand forming, throwing, and slip casting, among others. This article highlights how all of these techniques can be brought to the virtual world. Digital creative technologies are gaining maturity and now enable artists to reach greater heights. An example of imagineering that has come to fruition and fundamental to this article is sound shape modeling. Sound creates several detailed shapes when it interacts with clay and fluid. The artist would like to model those intricate shapes and patterns that are extremely difficult to create using the artist's hands.

This article focuses on virtual pottery modeling. The approach seamlessly captures the shape, interaction, and making in the artistic pottery process, albeit using digital creative tools. Computer graphics modeling over the past decades has shown a high demand for sophisticated realism of geometric shapes. Graphical shape modeling has found pervasive use in various fields, e.g., Arts, Medicine, Engineering, and many other fields. Digital technologies have also revealed a new path for contemporary art and creation. Today arts, science, and technology are united by a bridge of creativity, allowing cross-disciplinary fields to meet.

The impact of this bridge has created opportunities and challenges for a new innovative approach, enhancing and promoting existing experiences and outputs (Krasteva 2016). VR/AR painting and pottery making is the innovative beginning of advanced 3D modeling in art practice, opening the imagination to conquer realistic visual and physical real-world reality, to produce, share, and enhance skills. Clay based modeling is an ongoing trend for developers of 3D/AR/VR modeling to explore, expand, and develop. This method brings realistic deformation, representing real objects transformation, to the human visual concept that augments a more genuine and real visual appearance. Clay 3D modeling is a method that integrates digital deformation as simulation upon real geometric and physics data. It represents a 3D surface mesh sculpting with tools to push, pull, twist, inflate, surface relief, as well as a voxel-based geometry method to add/subtract.

Imagineering using computer graphics has not only enabled artists to visually interact with the creation of artistic objects, but also provide the essential link for fabrication to physicalize the artistic creations. This on the surface looks feasible but needs to grow in maturity to process and transform the visual form to physical form. This requires a detailed understanding of the processes in manufacturing and even more detailed understanding of the materials and their properties for ceramic fabrication.

Background

Virtual Deformable Shape Modeling in Fine Art

Virtual reality modeling is one of the cutting-edge creative technologies that support deformable shape modeling, using physical interaction data to enhance objects by color, depth, and deformation. One of the examples is volumetric modeling introduced by Kim et al. (2018). The authors demonstrated a high-resolution method of volumetric painting in virtual reality with high depth complexity. The technique consists of digital painting on 2D surfaces extended into 3D volumetric painting.

Ioana also examined another method using Tilt Brush. It is a VR painting application produced by Google as collaboration between artists and

scientists, enhancing creative practice opportunity for users and their 3D artwork created VR space with sharing creations online. More so, turning the 3D VR object into a holographic format for the wider public (Pioaru 2017).

An exploration on virtual clay modeling and tools was presented in the literature (Sener et al. 2002). The authors investigated attempts offered on using haptics for force-feedback that was used by Gribnau (1999). They also suggested using CAD tools to generate 3D objects using PHANToM haptic device's human-computer interface technology for users to touch and manipulate virtual objects, considering free-form for a better development process. Sener's approach gave a solid ground to develop the concept of VR clay modeling and prototyping. This approach supported the idea of integrating the system and methods to establish a VP novel system by Dashti et al. (2020a). The integrated 3D graphics toolkit software system showed new opportunities and challenges to enhance computer graphics and traditional pottery-making fields.

Why Deformable Shape Modeling?

Deformable shape modeling is a reliable, functional method for computer graphics, modeling a realistic volumetric geometric texture. This approach provides more accurate, pragmatic variable data of deformational behavior. The technique produces volumetric deformation of, e.g., height, depth, twist, and bend for medical scientists, artists, and engineers to enhance their performance and outputs.

Challenges in 3D Graphics Shape Modeling

Computer graphics modeling is considered expensive, as well as labor and compute-intensive. 3D modeling tools mainly creates rigid object surface with texture deformation to offer limited visual appearance of a detailed representation.

Deformable Shapes in Surgery Simulation

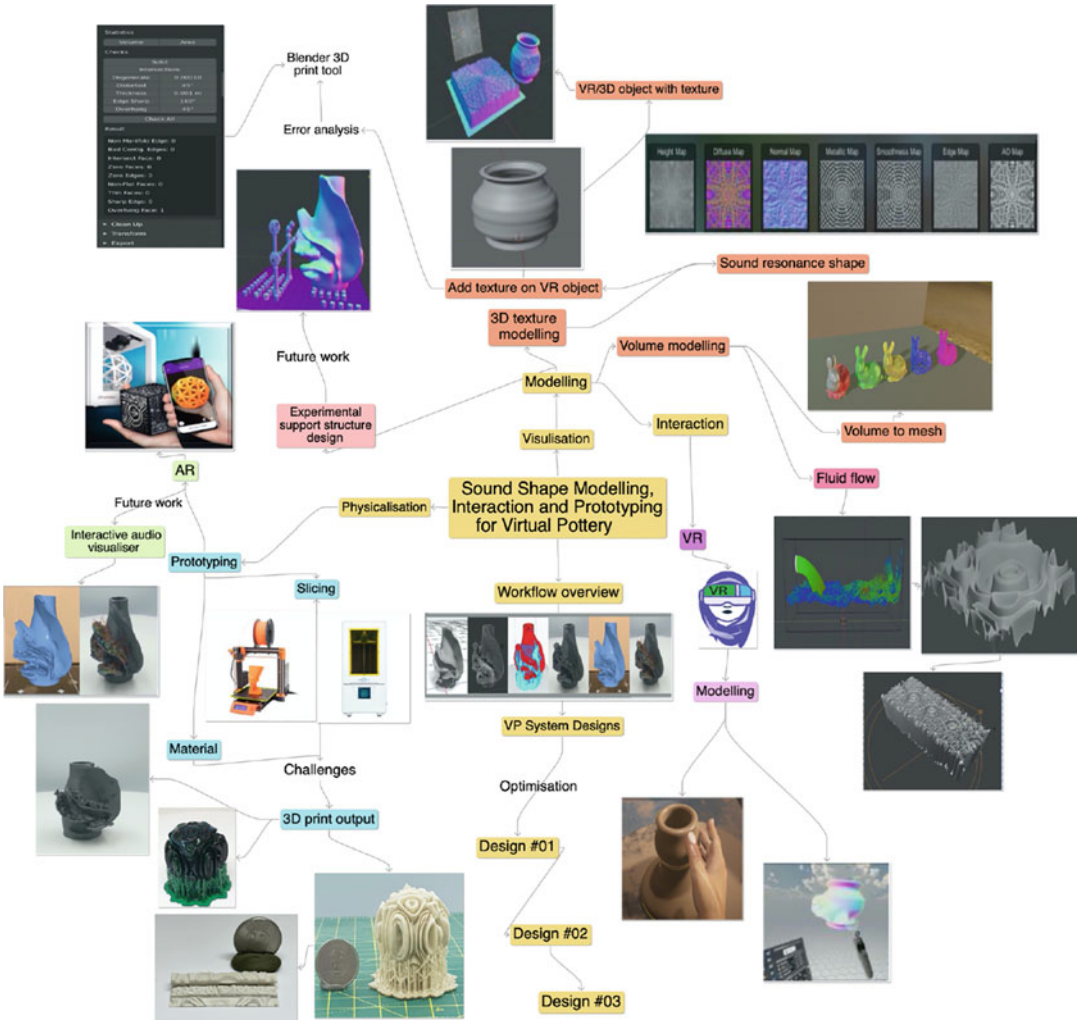
The approach for surgery simulation is an advanced deformation system that uses a parametric model by Liu et al. for Surgery Simulation. Haptics on 3D deformable models is a challenge because of the inevitable and expensive 3D deformation computation. In their paper, the authors proposed a technique that extends the conventional rigid approach using geometry images. Their approach flattens the geometry and also helps to accomplish deformation effectively and efficiently. They demonstrated that their method is suitable for haptics computing to perform the deformation on the geometry map to avoid expensive 3D deformation computation. They presented the construction of the deformable geometry map representation and its application utilizing practical methods for interactive surgery simulation and interactive textile simulation (Liu et al. 2007). This parametric approach has potential for the proposed Virtual Pottery application.

Deformable 3D Shapes in Facial Animation

Zhang et al. introduced a method of exploring the real natural deformation of a human face, using animated representation. The system relies on a physically based 3D facial model-based with anatomical knowledge. The approach involves a dynamic, non-linear multi-layered skin model where the skin is built as a mass-spring-damper (MSD) facial model (Zhang et al. 2004). In Chen and Prakash's face simulation (Chen and Prakash 2006), the authors use an animation system for a personalized human head. The deformation from the template model to the target head is through adaptation. Both general Radial Basis Function (RBF) and Compactly Supported Radial Basis Function (CSRBF) are applied to ensure the fidelity of the global shape and face features. Animation factor is also adapted so that the deformed model still can be considered as an animated head. Situations with insufficient scanned data are also discussed in their paper. A related approach by Navarro-Newball et al. (2011) builds up a face using anatomy guided bottom up creature skinning. These approaches have the potential for multilayered shape modeling for virtual pottery.

Deformable 3D Shapes in Artistic Simulation

Dashti et al. presented a demonstration of a novel method using off-the-shelf tools to discover unique texture for VP interactive modeling, a novel approach for virtual pottery, 3D modeling



Imagineering Ceramic Pottery Using Computer Graphics, Fig. 1 Imagineering the virtual pottery workflow

with augmented reality interaction technique for materializing deformable shapes sound-resonance on 3D objects. The technical framework provided a new method using simple processes to perform complex object transformations for virtual, 3D modeling and augmented reality interaction. Clay-based VR modeling uses the concept of deformable shape modeling to extend physical ceramics. It captures the visual and physical representation deformation of actual ceramic making (Dashti et al. 2020b). Clay as material presents some challenges of preserving real-world constraints, such as gravity and evaporation, capturing the artist's creative physicalized imagination. Figure 1 shows the different elements of imagineering for the virtual pottery system and captures the relation between the various aspects. Figure 2 shows an example of an object that has undergone the imagineering process and realized in a physical form.

This approach augments realistic shape and surface transformations, using 3D surface mesh sculpting with voxel-based geometry. The volumetric 3D Sound-Structure Texture Modeling process first includes materializing sound resonance from fractal images, using Chladni plate software with bump and displacement mapping. Next, volumetric deformable shape maps are

Imagineering Ceramic Pottery Using Computer Graphics, Fig. 2 Physicalized output from the virtual pottery imagineering system

blended on the surface of the VR object to combine intricate sound resonance patterns. The procedure is then extended to transform the output of complex 3D shape models from the above steps for rapid prototyping using appropriate pre-print tools by remeshing and physics manipulations.

Conclusion

The time has come for Imagineering Ceramics Pottery Using Computer Graphics. This work has highlighted the imagineering map with several elements seamlessly integrated. Challenges still remain where every element can be expanded with more realistic features. One specific area of immediate focus in this work is Imagineeramics, to look at the full functionality of imagineering with ceramic material properties. It is all in the imagination of the artist and computer scientist to push the boundary forward.

Immersive Auralization Using Headphones

Michele Geronazzo
Department of Architecture, Design, and Media Technology, Aalborg University, København, Denmark

Synonyms

Earphones; Headphone; Headphone impulse response; Headphone transfer function; Headphones; Headset

Definitions

Headphones are electro-acoustic transducers able to convert two electric output channels into two dichotic acoustic signals at user's ears, preferably binaural signals. The less distortion and flat response headphones hold the more control of sound parameters and auralization accuracy game developers and designers can obtain. Headphone-induced spectral coloration and distortion is a key factor in music listening but even more critical in future immersive virtual and augmented reality scenarios where users directly compare their real life sensory experience with realistic multimodal synthetic stimuli and interactions.

Introduction

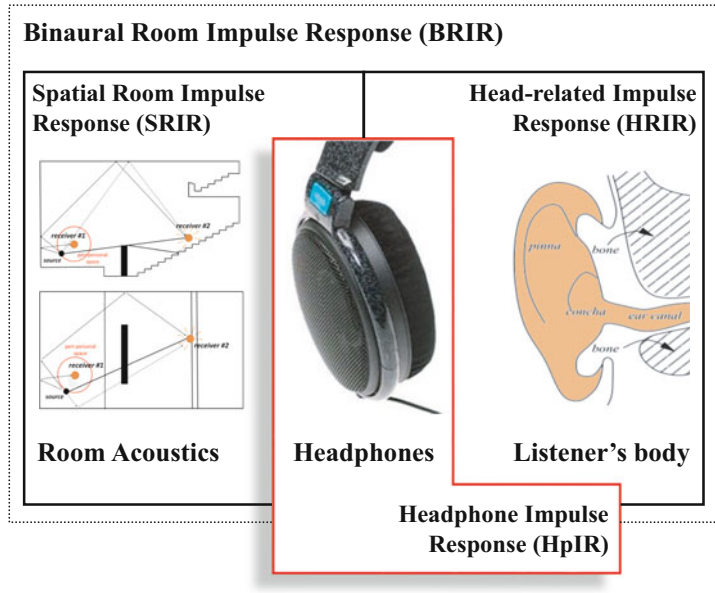
In order to deliver natural auditory experiences in virtual/augmented reality with headphones, sound pressure level (SPL) of the synthesized sound field has to be delivered at user eardrums coherently with their natural listening experience (see Fig. 1 for a general schematic view). In particular, auralization algorithms should rely on a well calibrated audio equipment and individually equalized headphones (see "▶ Sound Spatialization").

Sound transmission from headphone to eardrum can be represented through an analogue circuit model (Møller 1992) with the ideal goal to obtain:

$$Z_{\text{headphone}} \approx Z_{\text{radiation}}, \quad (1)$$

where $Z_{\text{radiation}}$ denotes the equivalent acoustic impedance outside the ear canal in free-field listening conditions, and $Z_{\text{headphone}}$ the equivalent impedance outside the ear canal with headphones. This equation can be interpreted as follow: the opposition that headphone present to the acoustic flow, i.e., playback audio signals inside ear-canals, should be comparable to natural listening conditions without headphones. The validity of such model is restricted to wavelengths greater than the ear canal's width, i.e., approximately under 10 kHz, leading us to define the so-called Pressure Division Ratio (PDR) as the ratio between the pressure divisions of two situations:

- Open/blocked ear in a natural listening conditions with an external sound source in anechoic space
- Open/blocked ear when the sound source is the headphone driver



Immersive Auralization Using Headphones, Fig. 1 High-level acoustic components for VR auralization with focus on headphone interaction

One can formally define the PDR as follow:

$$\frac{P_{\text{open}}}{P_{\text{blocked}}} = \frac{P^{Hp}_{\text{open}}}{P^{Hp}_{\text{blocked}}}, \tag{2}$$

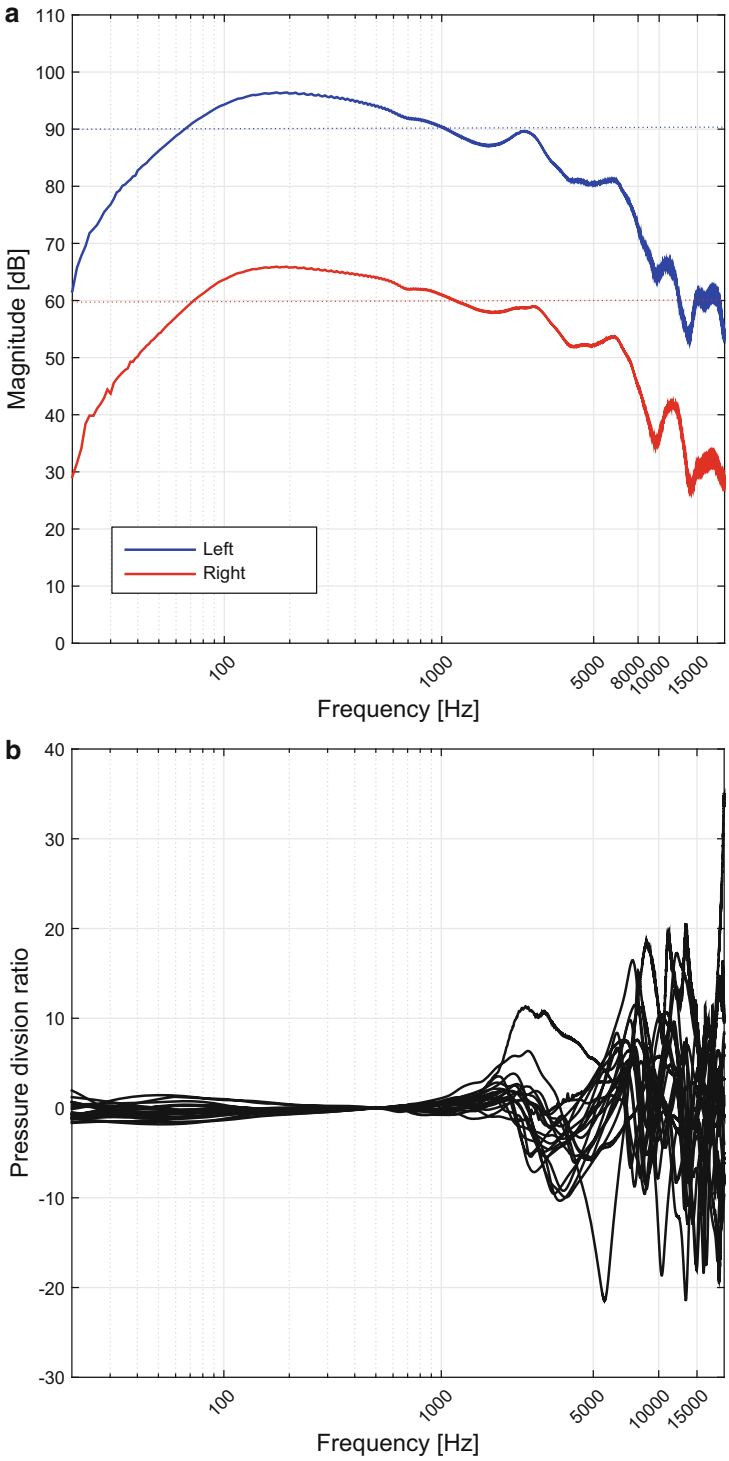
where P_{open} and P_{blocked} stand for the free field sound pressure at the entrance of the open- and blocked-ear canal, respectively, while P^{Hp}_{open} and P^{Hp}_{blocked} indicate the same sound pressure observation points when the sound source is a headphone. Figure 2b depicts an example of PDR computation for 18 users. Headphones with PDR ≈ 1 satisfy the free-air equivalent coupling (FEC) criterion (Møller 1992) where the acoustic load to the ear canal is equal to the radiation impedance of ears without headphones. Headphones act as an acoustic cavity that introduces a constant level variation at low frequencies, i.e., ≈ 4 kHz, with few inter-subject variability. On the other hand, headphone position and user's external ear anthropometry introduce frequency notches in the higher spectrum. Headphone- and user-specific acoustic interferences are difficult to predict and compensate in order to have a robust flat headphone response for auralization.

Sources of Variance in Binaural Signals

Audible artifacts and unnatural spectral coloration are likely to occur in the reproduction of binaural signals with headphones. In Brinkmann et al. (2017), a summary of main sources of error was reported taking into consideration authenticity of audio rendering, i.e., the perceptual identity with a real acoustic event (Blauert 1983). In Table 1, only key factors and average acoustic errors related to headphones are reported.

It has to be noted that the major sources of error are headphone repositioning and presence. The first source is closely related to headphone form factors and robustness to movements, while the second mainly affects comparisons between natural listening experience and binaural audio rendering with headphones in tests on authenticity where participants are usually asked to evaluate both conditions without removing and putting headphones on.

The mix of standing waves that start to grow inside headphone cups, with outer ear's resonances, results in an individual characterization of headphone acoustics. Headphone form factor (i.e., circum-aural, supra-aural, extra-aural, earbuds, and inserted) heavily influences all these sources of variation. Headphone acoustic



Immersive Auralization Using Headphones, Fig. 2 Example of headphone transfer function for SENNHEISER HDA200 supra-aural headphones over a 20 human heads; data are taken from BT-DEI HPIR database, part of the PHOnA archive (Boren et al. 2014). (**a**) Average magnitudes considering all 18 individual HpTF sets with reference calibration 90 db_{SPL} at 1 Khz (dashed blue line and $-$ 30 db_{SPL} shifted dashed red line are left and right channels, respectively), (**b**) variability on pressure division ratio across human heads

contribution can be described by headphone impulse response (HpIR) measurements or their frequency domain counterpart, i.e., headphone transfer functions (HpTFs). HpIRs are typically measured on an (i) artificial ear (e.g., B&K 4153), (ii) a dummy head (e.g., KEMAR mannequin

Immersive Auralization Using Headphones, Table 1 Sources of errors and variance due to headphones for binaural reproduction

	Typical error (dB)	Maximum error (dB)
Headphone repositioning	5	20
Acoustic headphone load	4	10
Headphone presence	10	25
Headphone compensation	1	10

(Gardner and Martin 1995)), or (iii) human listeners. Since, the first two measurement methods do not consider inter-subject and intra-subject variability, individual recordings should be preferable in order to take into account multiple positionings of headphones and to fine tune headphone compensation algorithms for a specific user. However, this latter approach is not practicable for a wide population of users; accordingly, headphone equalization algorithms usually rely on average HpIR responses for compensation which is based on available measurements for a specific headphones on a group of users thus accounting only for headphone contribution (see Fig. 2a for an example); moreover, regularization methods act on high-frequency gain in order to further level out user-dependent variations (Schärer and Lindau 2009).

It has to be noted that virtual and augmented reality applications require different headphone levels of isolation or transparency making the choice of a proper headphone design and equalization algorithm critical. Since noise-canceling headphones can be considered an extreme example of acoustic isolation from the real world, hear-trough devices require all the external acoustic information to be collected and processed together with virtual sound sources (Valimaki et al. 2015).

A high level of authenticity for a virtual auditory display can be achieved using extra-aural headphones where the acoustic coupling between listener and headphones is minimized (Romigh et al. 2015), thus resulting in less influence of the playback device on a recorded/synthesized sound-field; however, external sound sources easily interfere with auralization, and head movements could cause large variations in placement of suspended headphones, thus leading their use for only research purposes. On the other hand, the scientific literature suggests that circum-aural Sennheiser HD600 is usually adopted as a de facto standard for a broad variety of psychoacoustic studies on binaural reproduction. This headphone model fulfills FEC criterion; however, it do not allow isolation from external sound sources. In order to overcome the isolation issue, in-ear headphones seem to introduce smaller intra-subject variability (less inclusion of pinna contribution) once the quality of the sealing is high (Olive et al. 2017), at the cost of a nontrivial compensation for ear occlusion.

Conclusion

Auralization relies on the amount of individualization in the headphone correction of both measurement techniques (e.g., average, generic, and individual HpIRs) and equalization methods with emphasis on high-frequency control in the inverse filtering problem (Boren et al. 2015).

In-situ individual calibration for a transparent headphone response is a challenging research issue with no straightforward procedures, especially for inserted earphones that do not satisfy FEC criterion. Novel technological advances are contributing to the integration of headphones in even more smart headset, introducing a binaural earphone-plus-microphones system which will be able to extract the ear-canal transfer function (ECTF) in real-time and to perform an adaptive inverse filtering able to estimate sound pressure of an occluded ear canal (Denk et al. 2017).

Immersive Technologies for Accessible User Experiences

Alvaro Uribe-Quevedo
Software Informatics Research Centre, University of Ontario Institute of Technology, Oshawa, Canada

Synonyms

Extended reality; Usability; User experience

Definition

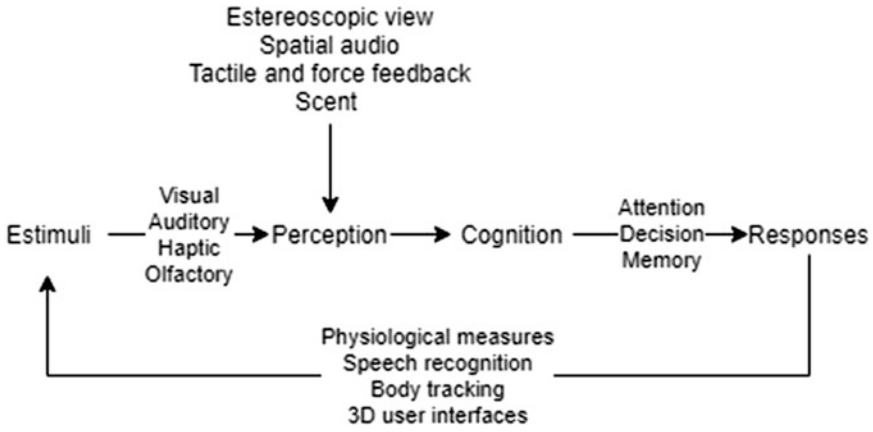
Immersive technologies encompass hardware and software that provide sensory feedback in the form of visual, auditory, haptic, or olfactory cues employing diverse human interface devices. Coupled with human-centered design considering varying human factors associated with perception, cognition, and physical ergonomics, these technologies aim to provide accessible user experiences. Although accessibility is typically associated with removing barriers for those experiencing disabilities, usability should be used instead because its purpose is the ease of use regardless of the end-user.

Introduction

Immersive technologies enable cross-sensory experiences that blur the frontier between virtual and real worlds (Suh and Prophet 2018). The cross-sensory stimuli are also referred to as multimodal or cross-modal because of the use, combination, integration, or translation of sensory cues into diverse installations (i.e., artistic, educational, training, or health care, among others), which affect the user experience (Kapralos et al. 2017). Currently, Virtual and Augmented Reality, VR and AR, respectively, are becoming ubiquitous with off-the-shelf products including mobile devices, video game-handheld devices, and headsets, which are becoming readily available. Furthermore, there are several high-end and industry-grade immersive technologies, for example, Mixed Reality (MR) devices such as the Microsoft HoloLens 2 offer holographic projections blended into the real environment, which are currently used in medical, defense, and automotive applications (Speicher et al. 2019). Although VR, AR, and MR can provide highly immersive and engaging user interactions, these technologies typically offer isolated experiences, and recent trends favor social symmetric and asymmetric experiences (i.e., those were users share the experience using the same technology or different devices, respectively) (Jeong et al. 2020). The interconnectivity of these immersive technologies is allowing cross-platform interactions, where VR users can interact with those using AR or MR thus producing eXtended Reality (XR) experiences (Skarbez et al. 2021).

Immersive technologies interconnect human factors within interaction loops. The users will process the perceptual information to make decisions and interact with the virtual environment while receiving sensory feedback as shown in Fig. 1. Depending on the experience (e.g., leisure, entertainment, training, or education), actions or information may be stored in either the short- or long-term memory. Within the interaction cycle, attention influences how the users gather spatiotemporal information. Attention is required for the orientation of sensory events and detection of signals for processing, which has been predominantly achieved through visual stimuli (LaViola et al. 2017).

The perceived visual, auditory, and haptic stimuli allow users to act and execute tasks through a combination, substitution, or translation of sensory cues. This is required in order to compensate for the limitations of immersive technologies with respect to providing realistic perceptual information. For example, the lack of visual feedback for localization tasks can be replaced by auditory cues (Massiceti et al. 2019), and the combination of haptic and auditory cues can further enrich localization skills for those with vision impairment (Reynal et al. 2019). The cross-sensory cues enable mental processes associated with thinking, remembering, and decision-making, also referred to as



Immersive Technologies for Accessible User Experiences, Fig. 1 Interaction loop

cognition. The cognition process can be further understood by analyzing in-experience metrics such as time to completion, task completion, and information from physiological sensors including eye tracking, heart rate, brain activity, muscle activity, and skin responses (Fralish et al. 2018).

A meta-analysis on AR in education highlighted the importance of the acquisition of social, living, learning, and physical skills for users with cognitive disabilities (Baragash et al. 2020). A recent study into VR adoption in K-12 for students with disabilities revealed the prevalent use of non-immersive screen-based interventions that do not take advantage of the immersive and interactive capabilities of immersive VR (Carreon et al. 2020). The current availability of consumer-level XR technologies has sparked interest in developing accessible user experiences through customized interactions employing speech recognition (Bryant et al. 2020), body tracking (Shao et al. 2020), gaze tracking (Saha et al. 2019), and custom-made human interface devices (Mirzaei et al. 2020).

Visual Perception Technologies

Predominantly, the visual domain is the most used in immersive technologies and has seen the most advances. Immersive visual cues rely on the capacity to perceive depth, which is achieved by VR headsets employing stereoscopic views seen through biconvex lenses. Figure 2a presents the Oculus Quest 2, a VR headset featuring inside-out tracking for seated, standing, and room-scale VR. The ability to customize the interactive volume allows using VR as a portable solution for travel training for people with intellectual disabilities (Checa et al. 2019). Figure 2b presents the Aryzon AR headset, which uses an array of mirrors that create the effect of holography, and unlike traditional AR, the Aryzon headset is hands-free. AR is the immersive technology which is the most widely available to users as it can be used with most medium-range mobile devices, including phones and tablets. AR has been used to facilitate wheelchair indoor navigation by informing users about obstacles and hazards in planning safe routes (De Oliveira et al. 2017). Additionally, AR has been used to help those with dyslexic impairment to decrease the overall time required for reading by enabling text customization adjustments, including background contrast among others (Gupta et al. 2019). Finally, Fig. 2c presents the Microsoft HoloLens, a headset that overlays virtual content in the real world by mapping the environment, thus creating holographic visual feedback. User interactions occur through remote control, hand tracking, voice recognition, and eye tracking.

Within the field of visual immersion, holographic displays are gaining momentum due to their capacity of providing visualizations with depth to multiple users without requiring a

headset. Nonimmersive displays enable users who cannot use a headset to experience the virtual content. Figure 3 presents two views from a living room scene rendered on the Looking Glass holographic display for reminiscence therapy, an intervention that helps individuals with dementia to recollect memories from their past (Tabafunda et al. 2020).

The use of holographic displays and tethered VR and MR HMDs requires a VR-ready computer, which makes this solution accessible to few users. A consumer-level solution to this problem is using nonimmersive VR where users navigate the environments through a regular screen. The addition of motion parallax effects concerning the user's head position and orientation can be used with regular screens to provide depth perception. Figure 4 presents the nonimmersive VR motion parallax implemented with a web camera, the FaceTrackNoir library, and the Unity game engine. Figure 4 shows how the foreground tree occludes the cherry blossom when moving from left to right. Similar motion parallax effects can be achieved employing depth sensors such as the Azure Kinect for providing more realistic telepresence human interactions (Tölgyessy et al. 2021).

Visual Tracking Technologies

Measuring and driving user interactions employing eye tracking for understanding human cognition in immersive technologies is a relatively novel field. Eye tracking allows capturing information associated with gaze, regions of interest, and attention span (Clay et al. 2019). Recently, advances in eye tracking have led to the use of foveated rendering for improving attention and rendering optimization by increasing the visual fidelity of the areas of interest where the gaze is attending (Matthews et al. 2020). Concerning accessibility, Masnadi et al. (2020)

developed an eye-tracking assistance tool that projects corrections designed to help people with visual impairments.

Currently, off-the-shelf VR devices offering eye-tracking capabilities include the HTC Vive Pro Eye and Pico Neo 2, both featuring Tobii eye-tracking technology. Pupil Labs also offers eye-tracking add-ons that can be attached to various immersive technology hardware including Microsoft HoloLens 1 and eyewear for AR. In contrast to the Microsoft HoloLens 1, the Microsoft HoloLens 2 integrates eye-tracking technology without requiring additional hardware. Figure 5 presents a view of the HTC Vive Pro Eye and Pico Neo 2.

Auditory Perception Technologies

Second to vision, auditory cues provide perception of direction and distance from the audio source. Spatial audio applies directional audio filters by adjusting the frequencies and delays of what is heard by each ear (Tashev and Gamper 2017). The output causes the sensation of hearing sound from different directions when navigating the virtual environment, which can be used as travel aids for visually impaired users (Spagnol et al. 2018). Spatial audio can also be used to increase empathy and awareness concerning activities performed without visual cues (Guarese et al. 2021). For example, Cowan et al. (2020) developed a framework for analyzing the effects of sound rendering in a virtual environment, where participants navigated a virtual world through the localization of audio sources, concluding that improvements in spatial audio rendering do increase task performance.

Except for mobile AR, current VR, and MR, HMDs feature spatial audio through embedded speakers either on the headband (e.g., Oculus Quest, Oculus Rift S, and Microsoft HoloLens), or ear speakers hovering on top of the ear (e.g., Valve Index). As a result of advances in binaural rendering and sound-based physics, spatial audio provides more accurate auditory representations than stereo or surround sound, which is limited to environmental recordings on multiple channels. Because of these properties, spatial audio can be used as a substitute for visual cues to help users

with various degrees of sight loss to navigate virtual environments, such as a virtual conference venue (Robern et al. 2021). Research in this field has produced methods for mapping visual navigation to auditory cues employing echolocation and distance-dependent hum volume modulation (Massiceti et al. 2019).

Speech Recognition Technologies

Speech recognition plays an important role in immersive interactions as it allows to create more natural user-avatar interactions by facilitating speech-to-text, text-to-speech, and enabling automated dialogues driven by emotion recognition, physical interactions, and physiological measures (Cinieri et al. 2020). A review conducted by Nassif et al. (2019) identified the prominent use of machine learning in English settings determining efficiency through word-error-rate, concluding the need for employing recurrent neural networks to yield better results. For example, Teófilo et al. (2018) developed a system that employs language to assist deaf and hard of hearing users to improve speech understanding by supporting sentence prediction and spelling correction. Artificial Intelligence (AI) has been renewed in speech recognition thanks to the advances in smart assistants in mobile phones and smart assistants as it allows for creating natural user interactions to help users with disabilities interact with the virtual environment, whether for avatar interactions to help users with autism to better understand emotions through audiovisual cues (Yuan and Ip 2018) or facilitating communication through the interpretation of sign language (Cheok et al. 2019).

Somatosensory Perception Technologies

Kinesthetic and proprioceptive cues, pertaining to the somatosensory system, allow for the feeling of textures, object properties, objects in motion, and a perception of self. Within this system, haptic feedback or the sense of touch plays an important role in immersion and presence as it enhances perception to the point that it can be used to replace visual and auditory feedback. Sorgini et al. (2018) conducted a literature review on haptic technologies for auditory and visual sensory disabilities, where it highlights the importance of sensory substitution employing consumer-level technologies to facilitate interactions with nondisabled peers.

Vibrotactile feedback is the most commonly used technology due to the miniaturization of actuators, its low-cost, and the seamless integration inside VR controllers, gamepads, clothing, and custom-made 3D-printed user interfaces. For example, virtual environments can be coupled with a walking cane to provide auditory and haptic cues to enable training and increase awareness when navigating unknown locations (Zhao et al. 2018). Kim et al. (2021) developed a human-display interface with vibrotactile feedback for assistive applications such as devices relying on touch screens found in vehicles, wheelchairs, and public locations such as airports, hotels, and shopping malls. Vibrotactile feedback is limited to cues associated with vibrations, taps, pressure, and pinching feedback through skin deformation. This limitation of vibrotactile feedback impedes the capture of Kinesthetic cues that allow determining the physical relationship with objects. Force feedback haptic devices, on the other hand, require mechanisms that transfer mechanical movement to the user through actuators that respond to the user's inputs.

Wearable haptic devices for visually impaired users provide AR installations featuring gesture tracking and haptic gloves that enable computer interactions including writing emails, storing and retrieving files, making video calls, and accessing email, among others (Kalra et al. 2021). Theil et al. (2020) developed a tactile board for users who are both deaf and blind as a tool for translating text and speech into vibrotactile cues displayed through a wearable haptic user interface. Wang et al. (2018a) developed an intelligent wearable controller for people with motor disabilities employing machine learning and noninvasive sensors to drive computer interactions based on eye muscle movement and facial expressions.

Olfactory and Taste Perception Technologies

Finally, olfaction and taste respond to chemical cues that are underrepresented in immersive technologies as these mainly provide feedback that is difficult to register. While significant technology development is lacking in this area, olfactory feedback in VR has been investigated as it can add immersion and presence to the user experience by providing alerts, reinforce learning, and evoke memories and emotion. Casillas-Figueroa et al. (2020) conducted a study to assess the effectiveness of olfactory feedback in reminiscence therapy to provide additional feedback to the users.

Ergonomics

Ergonomics focuses on ensuring that the interactions are usable and effective with respect to the user's anatomy and physiology. Higher physical levels of immersion require taking advantage of human interface devices that capture the user's body and their interactions within the virtual environment. Currently, hand tracking is readily available in consumer-level VR through image processing (e.g., Oculus Quest and Microsoft HoloLens) as is finger tracking through proximity sensors (e.g., Valve Index controllers). Shao et al. (2020) developed a system for teaching American sign language in MR with noticeable improvements when compared to computer desktop learning. However, image processing with hand tracking lacks accuracy in comparison to data gloves that allow capturing dexterity more accurately (Ahmed et al. 2018). Furthermore, some gloves integrate diverse actuators to provide thermal, haptic, and force feedback (Wang et al. 2018b).

Locomotion is another field of interest as it enables users with limited mobility to experience virtual navigation. Virtual walking is typically achieved by means of head tracking, arm swinging detection, and custom-made foot-user interfaces in conjunction with 3D-user interactions such as teleportation (Cherni et al. 2020). However, it can also be accomplished by other input mechanisms including eye tracking, muscle activity, brain activity, speech recognition, or body gestures.

Although body capture is used to facilitate the interactions, users who experience limited mobility may require additional input devices to execute the virtual tasks. For example, brain-computer interfaces allow capturing cerebral activity that can be used to interact with virtual elements. Coogan and He (2018) proposed a modular system that allows users to customize the interactions based on their brain activity to empower users with autonomy. Bobrova et al. (2020) captured imaginary lower limb movements through a brain-computer interface as means to enable VR locomotion. Further customization employing physiological sensors is becoming readily available in VR and MR headsets, as well as mobile devices for AR.

Conclusion

Immersive technologies have shown their disruptive potential in changing how we engage with education, entertainment, fitness, and training. While the benefits have been documented toward the average user, the landscape is rapidly changing as researchers, developers, and enthusiasts have started developing inclusive experiences. The affordability of XR devices has increased the number of users who install base and sparked interest in sectors that were unable to use them due to costs or infrastructure requirements.

The adoption of XR has allowed to identify several areas of research associated with usability, user experience, body tracking, locomotion, motion sickness, user interactions, cognitive load, security, and presence, among others. While the hardware may come as one-size-fits-all, researchers are creating innovative solutions leading to novel devices, techniques, retrofitting, reverse engineering, and customization of immersive technologies for accessible user experiences.

Definition

Computer simulation	A recreation of real-world phenomena employing mathematical models that can be visualized through a computer-generated scene.
Immersion	Sensation of being in a computer-generated world created by surrounding hardware providing sensory stimuli. Can be a purely mental state or can be accomplished through physical means.
Presence	The feeling of being immersed in a computer-generated world.
Immersive technology	Devices that provide sensory stimuli to provide a sense of realism and immersion to the interactions with the computer-generated world.
Virtual reality	An interactive computer simulation which senses the user's state and operation and replaces or augments sensory feedback information to one or more senses in a way that the user obtains a sense of being immersed in the simulation (virtual environment).
Augmented reality	The addition of computer-generated objects to the real physical space to augment the elements comprising it.
Mixed reality	Integration of computer-generated graphics and real objects seamlessly.
Serious game	A video game whose primary purpose is education, training, advertising, simulation, or education as opposed to entertainment.

Introduction

Traditionally, medical education has followed the time-honored concept of "see one, do one, teach one," where theoretical education is followed by supervised clinical practice (Riener and Harders 2012). However, this approach is no longer viable and becoming less acceptable given the increasing focus on patient safety, care, and awareness, along with budgetary constraints associated with teaching in a clinical environment, particularly when considering invasive procedures that require high-risk care (Vozenilek et al. 2004). This increased awareness and focus on patient safety has been encouraged by studies that have examined medical errors and have suggested that as many as 98,000 Americans and 23,000 Canadians may die each year due to medical errors. Although the precise numbers have been debated, without a doubt, medical errors affect patient outcomes and health-care costs (Brindley et al. 2007). A proposed solution is a shift from the traditional "see one, do one, teach one" apprenticeship model of education to one where the transition from theory to practice is augmented by carefully designed simulated encounters with patients, teams, and health systems. Termed simulation-based education (SBE), this approach enables a replication of most clinical situations with various degrees of fidelity or realism, multimodality, immersion, and presence (Brindley et al. 2007). SBE can offer a viable alternative or complementary mean to practice a range of skills, attitudes, and behaviors ranging from cognitive, to communication, to crisis resource management, and to psychomotor to be developed by junior trainees or maintained by more experienced doctors (Brindley et al. 2007).

Per Halamek et al. (2000), simulation involves immersing the trainee in a realistic situation (scenario) created within a physical or virtual space (simulator) that replicates the real environment. In the context of medical education, simulation can be defined as an education technique that allows interactive and immersive activity by recreating all or part of a clinical experience without exposing patients to the associated risks (Perkins 2007). It has two components: the scenario and the simulator. The scenario is a description of a simulation that includes the goals, objectives, feedback or debriefing points, narrative description of the clinical simulation, staff requirements, simulation room setup, simulators,

props, simulator operation, and instructions for SPs (Alinier 2011). The simulator, on the contrary, is a setting, device, computer program, or system that performs simulation (Hancock et al. 2008), and can include manikins, cadavers, animals, devices, technologies, computer programs and virtual spaces, scenarios, standardized patients, and a host of other methods of imitating real-world systems (Curtis et al. 2012).

Simulation in medical education is a well-established pedagogical practice (Reznick and MacRae 2006). It provides a viable alternative to practice with actual patients, providing medical trainees the opportunity to train until they reach a specific competency level. Simulation ranges from decontextualized bench models and virtual reality (VR-)-based environments, to high fidelity recreations of actual operating rooms (Kneebone 2009). One of the prevailing arguments for using simulation in the learning process of trainees is the ability to engage the trainee in the active accumulation of knowledge by doing with deliberate practice, while it also allows for careful matching of the complexity of the learning encounter to the trainees' current level of advancement (Guadagnoli et al. 2012).

Although the economic evaluation in SBE is still in its infancy, recent reports suggest that the costs associated with this approach are high (Lin et al. 2017), yet if designed correctly they are cost-effective means of increasing the trainees' skills, knowledge, and attitudes (Isaranuwatchai et al. 2014). These costs are primarily related to the "simulator" part of the simulation equation. The simulation equipment and material costs are high due to low volume and costs of production. Finally, the depreciation, durability, and maintenance cost of the equipment also affect these costs. The purpose of this equipment is to allow the trainees to make errors and therefore the equipment wears out quickly. Another cost is that of personnel, which includes faculty members' time, confederate and actor training (Adler et al. 2016), administration staff and instructors, and a site champion to maintain interprofessional leadership, team management, evaluation of the program, and quality assurance of the training (Walsh and Jaye 2013). Finally, other costs include the maintenance of the simulation facility, often referred to as simulation laboratory. Collectively, although SBE has been shown to be an effective tool in providing new learning opportunities that lead to more skilled trainees and safer practice, it is expansive. Therefore, the field of SBE is in search of more cost-effective solutions which can augment the current educational practices.

Immersive Technologies

The technologies of video games, virtual worlds, and social networks have become collectively known as immersive technologies because of their ability to engage users of all ages, driving massive investment into technologies to attract, capture, and retain our attention (Wortly 2014). The increase in computational processing power and accompanying decrease in the size of electronic components has led to the decreasing cost and rising availability of consumer-level immersive technologies which have helped advance the adoption of virtual simulation in recent years. For example, hand and arm tracking technologies accomplished with controllers such as the Leap Motion hand sensor, the Razer Hydra, and the Thalmic Labs Myo interaction device are allowing for the development of novel interaction methods and techniques. Devices such as the Microsoft Kinect V2 motion sensor can track the position of the user's body and precisely track the movement of individual fingers in three-dimensional (3D) space. Haptic input devices such as the Novint Falcon or the 3D Touch Stylus provide a sense of touch and feedback to motion controls. Collectively, these devices provide more natural and immersive interactions, which in many applications help overcome the limitations associated with traditional keyboard and mouse-based human-computer interactions where tasks are performed very differently to a real-life situation. The current trend on natural user interactions is providing the designers and developers of virtual simulations with tremendous freedom and opportunities to develop highly immersive applications. The field of immersive/interactive multimedia applications (including virtual

environments (VEs) such as video games, virtual simulations, virtual reality, and serious games, that is, video games whose primary purpose is education, training, advertising, simulation, or education as opposed to entertainment), has seen significant advancement over the last couple of decades. The field of virtual reality alone is estimated to grow from $1.37 billion (USD) in 2015 to $33.90 billion (USD) by 2022 (Markets and Markets 2016), while a recent estimate by Goldman Sachs suggests the fields of virtual and augmented reality are expected to grow into a $95 billion market by 2025 (Hall and Takabashi 2017).

Current VR installments are seeing implementations in different areas given the possibilities to have users interact in safe, controlled, and monitored environments. Mihelj et al. (2014) define VR as "an interactive computer simulation, which senses the user's state and operation and replaces or augments sensory feedback information to one or more senses in a way that the user obtains a sense of being immersed in the simulation (virtual environment)." Virtual reality has also been defined as "the use of computer modeling and simulation that enables a person to interact with an artificial three-dimensional (3-D) visual or other sensory environment" (Riener and Harders 2012). At a minimum functionality, VR systems typically utilize a head mounted display (HMD), as the primary method for a user to view and interact with a virtual world. A HMD is a display device worn on a user's head which uses optical lenses and one or two small displays to show computer-generated imagery. These headsets typically use various sensors embedded in the device (such as accelerometers or gyroscopes) to translate real-world movement and rotation into corresponding changes of the view of the virtual world. A capability currently supported by modern mobile devices, whose sensors and mobile HMD provide consumer-level VR. Within the taxonomy of VR, mixed reality (MR), augmented reality (AR), and mixed reality providing various degrees of real and computer-generated images integration (Milgram and Colquhoun 1999). This scenario has caused interest in training and education due to visualization opportunities to enhance, complement, and augment the immersive scenario. Moreover, in medical applications AR has allowed visualizing medical data and the patient within the same physical space (Sielhorst et al. 2008). The skills acquired during virtual reality-based simulation training have been proven to transfer over to subsequent performance in operating rooms (e.g., see Seymour 2008).

During the last few years, there has been an explosive growth of interest in consumer-grade VR technologies, in part due to gaming and entertainment applications, with several players such as Facebook, Microsoft, and HTC investing in hardware and software to increase the VR install base. Since then, various competitors, including various technology company giants, have entered the marketplace. For example, Samsung has designed and developed the Gear VR, an inexpensive headset which uses the owner's mobile smartphone as the display and system processor. Sony developed the PlayStation VR which integrates seamlessly into the Sony PlayStation 4 console platform. At the Apple Worldwide Developers Conference (WWDC) 2017, Apple introduced the ARKit, an augmented reality platform that provides advanced augmented reality capabilities on iOS and will be supported by all phones that Apple releases. Facebook has acquired 11 AR/VR companies, stressing the company's view that VR and AR will "form the next frontier" (Hall and Takabashi 2017). The large investments and acquisitions by various large technology firms indicate that these technologies will become increasingly integrated with the platforms on which we consume content. The high-end consumer-grade VR option is currently held by Taiwan-based HTC's Vive device, a package including an HMD, two hand controllers, and two base stations used to track both the headset and controllers in a 3D volume of real-world space. In contrast to traditional VR ("seated") configuration where the user remains seated in a chair within the range of the motion tracking sensor, the HTC vive allows for room-scale VR whereby the user can freely move within the real world (e.g., walk around, face any direction, bend down to the floor), and have consistently tracked hand controllers within a wide space.

Traditionally, the video game industry has been the largest pushing influence of advancing certain technologies such as computer graphics and personal computer audio capabilities. This trend follows suit with the modern VR device companies specifically targeting video game players, with one such example being usable only with a video game console (the Sony PlayStation VR). Although video game players are historically early adopters of new, exciting, and expensive technologies, VR device companies should not neglect the possibilities in the space of serious games and virtual simulations for education and training. Modern consumer-grade VR devices are affordable, powerful, and will soon be adopted by the mass market. Although the strongest demand for immersive technologies currently comes from industries in the creative economy, and more specifically, gaming, live events, video entertainment, and retail, immersive technologies will find wider applications in industries as diverse as health care, education, the military, and real estate over time (Hall and Takabashi 2017). According to Huff and Saxberg (2009), immersive technologies – such as multi-touch displays; telepresence (an immersive meeting experience that offers high video and audio clarity); 3D environments; collaborative filtering (which can produce recommendations by comparing the similarity between your preferences and those of other people); natural language processing; intelligent software; and simulations – will transform teaching and learning by 2025.

Projections for the growth of the VR hardware industry are staggering, with some research firms suggesting the market will grow to $50 billion by 2021 (Sinclair 2016). This is driven largely in part by video game early adopters although VR and AR are rapidly entering into the medical education and health-care fields. Within the medical field, VR and AR are not so much technologies of the future but rather, of the present where researchers, doctors, and nurse educators are finding innovative ways to leverage immersive technologies and transform both health-care teaching and practice (Craig and Georgieva 2017). In fact, over time, it is anticipated that immersive technologies and VR/AR specifically will play a large role particularly under the following six medical-based applications (Gardner 2016): (i) education and training, (ii) surgical planning, (iii) telemonitoring, (iv) patient experience, (v) treatment and therapies, and (vi) augmented reality-enhanced surgery and patient care.

Examples of Immersive Technologies in Medical Education

Wilcocks et al. (2017) developed a virtual simulation of the angiogram procedure specifically to educate patients about the commonly performed angiogram procedure. Using an HTC Vive virtual reality headset, the patient is taken into a virtual catheterization (cath) lab and introduced to the angiogram procedure in a highly immersive, interactive, and engaging virtual environment. The goal of their simulation is to educate the patient about the procedure they will undergo and thus help reduce the fear often associated with the procedure, while increasing the patient's understanding and awareness, ultimately leading to greater patient outcomes (Fig. 1).

Shewaga et al. (2017) developed a room-scale epidural preparation serious game facilitated with an HTC-Vive headset that allows a user (trainee) to assume the role of a medical professional preparing to perform an epidural procedure (an injection into the epidural space around the spinal cord and spinal nerves). The serious game focuses on the cognitive aspects of the epidural procedure as opposed to the technical components, and more specifically, the steps of the procedure and what needs to be done at each step (e.g., reading a detailed patient anesthetic record, washing their hands, wearing proper operating room clothing, and gathering the various tools needed for the procedure and placing them onto a preparation tray). Using the epidural serious game, they conducted a quantitative and qualitative comparison between the usability, performance, and engagement of traditional desktop VR with a room-scale variation in order to develop a greater understanding of the differences between the two configurations and determine whether the additional requirements and resources

associated with a room-scale VR configuration is warranted. Their quantitative results revealed limited differences between the two configurations, although the room-scale VR configuration did lead to higher immersion, and was generally preferred more among the participants. Greater work remains to determine whether one configuration is superior, but their results highlight the importance of considering the limitations of computer hardware when designing serious games and simulations, particularly when utilizing VR devices. Designers and developers of virtual simulations and serious games should consider the effects of the hardware being used and the requirements imposed upon it by the desired visual fidelity of the simulation. Higher fidelity implies greater computational requirements which may not be readily available to the average computer user (a discussion regarding fidelity, multimodal interactions, and perceptual-based rendering as they pertain to serious games is available by Kapralos et al. (2017)) (Fig. 2).

Conclusions

As computing power expands, new human performance monitoring technologies evolve, and the cost of simulation equipment falls, all medical training programs will need to devote substantial curricular time to SBE (Reznick and MacRae 2006). With respect to computer simulation (or in-silico simulation, depending on which way we go), VR is currently capable of providing a wide range of immersive experiences through numerous hardware that can provide various forms of sensory stimuli to achieve presence. This is of outmost importance in all VR installments as proper depiction of the tasks may affect the engagement and successful results. Moreover, in medical training the VR installments require the interactions to be tailored to match real-life scenarios to guarantee that the skills and competence can be transferred to live settings. That being said, it is important to consider the limitations of computer hardware when designing serious games and simulations, particularly when utilizing VR devices. There are numerous open research themes in VR, given the continuous hardware evolution and the high variability of users who may have motion sickness, 3D stereo blindness, and disabilities that would require adjustment to current hardware or the creation of new one, while addressing usability issues.

The future of SBE will, without a doubt, focus on introducing computer-based simulation with immersive technologies as part of blended modality approaches. That is, the different simulation modalities such as task trainers, manikin-based, standardized/simulated patients, computer-based, virtual reality, and hybrid play different roles in the educational journey of the trainee. Based on research to date, one can speculate that the choices and the use of various modalities in tandem with other ones will relate to the level of trainees, learning objectives, availability of resources, and

Synonyms

Learning; Rehabilitation; Serious games; Training; Virtual reality systems

Definitions

Virtual Reality	A model of reality with which users can interact using senses such as sight, sound, or touch.
Immersive Virtual Reality	A type of virtual reality in which the user's complete view is surrounded by the synthetic environment, as if they had stepped inside the virtual world. It is usually distinguished by the high level of immersion and interactivity offered.
CAVE	The abbreviation of Cave Automatic Virtual Environment, which is a virtual environment consisting of cube-shaped projection screens on the walls,

	floors, and ceilings surrounding the user.
Video Game	A game that is played by interacting with images in electronic form generated on a device such as computer monitor or TV screen.
Serious Game	A video game with a purpose beyond entertainment such as teaching users a new skill or training users to improve their existing skills on a subject.

Introduction

Virtual reality has become a prevalent tool in various areas because of the advancements seen in recent years. Video games constitute the major application area for virtual reality. Video games can be categorized in themselves according to their aims, such as entertainment games and serious games. In this entry, advantages and disadvantages of virtual reality and scientific studies in the area of immersive virtual reality serious games that has been published in the previous 10 years (between 2007 and 2017) are mentioned. The databases used were: Google Scholar, ACM Digital Library, IEEE Xplore, Springer Link, and Elsevier. The following keywords were searched in these databases: "Virtual Reality Serious Games," "Virtual Reality Learning," "Virtual Reality Education," "Virtual Reality Training," and "Virtual Reality Rehabilitation."

Advantages and Disadvantages of Virtual Reality

Several advantages and disadvantages of virtual reality have been identified in various previous studies (Dautenhahn 2000; Goldsmith and LeBlanc 2004; Parsons and Mitchell 2002; Putnam and Chong 2008; Rizzo and Kim 2005; Strickland 1997; Wang and Anagnostou 2014; Sharp et al. 2007; Hale and Stanney 2014). Major advantages of virtual reality can be summarized as follows: higher level of interaction fidelity; high level of immersion; active participation within virtual worlds; practicing in a safe environment; real time alteration of several attributes and parameters such as task complexity, environmental properties, and speed; reinforcement through infinite repetition using an automated system and software; easy variation and customization of content, tasks, and scenarios; highly structured automated training; high level of control on provided stimuli; increased focus of interest by isolation from surroundings; high degree of visualization which especially helps with abstract concepts; real-time prompts and feedback; no severe consequences of mistakes made during training; automated data collection and the ability of replaying recorded sessions for reflection afterwards; automated assessment and reporting; being appealing to technology savvy population.

On the other hand, some major disadvantages of virtual reality can be summarized as follows: motion sickness; disorientation; nausea; isolation and low degree of social interactions; requirement of wearing hardware which may be uncomfortable; price of special hardware, even though the technology is significantly affordable nowadays as compared to the previous decades; latency and frame rate problems; claustrophobia; risk of injury that may be caused by surrounding physical objects; hygienic concerns for multiple users sharing the same headset.

Immersive Virtual Reality Serious Games

This section includes recent immersive virtual reality serious game systems that focus on learning, training, or rehabilitation. There have been several studies that present virtual reality systems for learning. However, majority of these studies did not include immersive virtual reality systems but included desktop monitor displays or single screen projections. Many studies were published earlier than the 10 years limit this entry imposed.

Some recent works on immersive virtual reality for education are mentioned next. Du has worked on an experimental immersive virtual

reality system within a classroom learning context aiming to replace the traditional single projected screens in classrooms for more effective learning (Du 2014). Angulo and Vasquez de Velasco have developed an immersive virtual reality simulation system as an aiding tool for architectural spatial experience design (Antonieta 2014). Izatt et al. have constructed an immersive virtual reality system which functioned as an application for visualization and data interaction with the main goal of introducing new physics students and members of public to physical concepts such as Super-K, Hyper-K, the T2 K experiment, and water-Cherenkov detectors (Izatt et al. 2014).

Another major area for immersive virtual reality serious games is training. There have been several studies in the area of improving social skills of challenged populations. Cheng et al. have worked on using immersive virtual environments to improve the following social skill aspects of children with Autism Spectrum Disorder: nonverbal communication, social initiations, and social cognition (Cheng et al. 2015). Matsentidou has developed an immersive virtual reality system for improving social skills of children with Autism Spectrum Disorder via social stories presented in immersive virtual environments (Matsentidou and Poullis 2014). Lorenzo et al. have worked on an immersive virtual reality system that aimed to improve social and executive decision-making skills of children with Autism Spectrum Disorder with tasks that focus on school- and home-based social activities (Lorenzo et al. 2013). Ip et al. have worked on an immersive CAVE-like virtual reality system for training social adaptation of school-aged children with Autism Spectrum Disorder in inclusive education settings (Ip et al. 2016). Park et al. have developed an immersive virtual reality system for training individuals with schizophrenia on social skills such as conversation, assertiveness, and emotion expression via role playing in immersive virtual environments (Park et al. 2011).

Another emerging area for immersive virtual reality serious games is vocational training, especially catering for challenged populations. Bozgeyikli et al. have developed an immersive virtual reality system for vocational rehabilitation of individuals with cognitive and physical disabilities on several transferrable job skills (Bozgeyikli et al. 2017). Yu et al. have worked on an immersive virtual reality system that aimed to train individuals with hearing impairments on CNC machine operation skills (Yu et al. 2016). Sohn et al. have developed an immersive virtual reality projection based system for vocational rehabilitation of individuals with schizophrenia within the contexts of convenience store employee and supermarket clerk (Sohn et al. 2016). Webster has worked on an immersive virtual reality system that aimed to teach basic corrosion prevention and control knowledge skills to the US Army soldiers (Webster 2014).

Rehabilitation is another emerging area that includes several virtual reality studies. Some recent studies of immersive virtual reality rehabilitation systems are as follows: Maskey et al. have developed an immersive virtual reality system and utilized it along with cognitive behavior therapy to reduce some forms of phobia and fears such as crowded buses and pigeons in young people with Autism Spectrum Disorder (Maskey et al. 2014). Rooij et al. have worked on an immersive virtual reality system for improving balance and/or gait in rehabilitation of individuals after stroke (Rooij et al. 2017).

Limitations

This entry includes immersive virtual reality studies that were published in the last 10 years (2007–2017) and had a focus of learning, training, or rehabilitation applications. This entry does not include the following: entertainment games; commercial games; medical, military, or exercise serious games; and nonimmersive virtual reality studies that included desktop monitor, TV, or single projector displays.

Conclusion

The recent works mentioned are intended to give a snapshot of scientific studies in the area of immersive virtual reality in learning, training,

and rehabilitation. It was observed that the majority of the studies were catering for challenged populations. The diversity of application areas even within the three selected subtopics (learning, training, and rehabilitation) is encouraging for future studies in the area of immersive virtual reality serious games.

Synonyms

Augmented reality; Data visualization; Immersive technologies; Information visualization; Virtual reality

Definition

Immersive visualizations refer to a novel way of representing data and information through spatial computing technologies such as augmented and virtual reality. It aims to enhance the user perspective for enhanced insights from data and information to assist in the various processes including but not limited to decision making, enhanced learning, higher precision, and cost savings.

Introduction

Immersive technologies such as augmented reality and virtual reality have a transformational effect on how complex data and information is visualized. This trend has led to several applications across industries to adopt immersive visualizations. The reality-virtuality continuum has served as a reference framework for classifying different immersive technologies. The continuum was a continuous scale ranging between the completely virtual and completely real environment with visualization and immersion as the primary influencers (Milgram et al. 1995) (Fig. 1).

In this context, augmented reality, typically called as AR, is a technology that superimposes digital content on a user's view of the real physical world. It provides a composite view through a device such as a smartphone, a tablet, or a smartglass. The AR has core capabilities of information visualization, guiding the user and making the environment interactive through mediums such as gestures and voice (Porter and Heppelmann 2017). Latest developments in smartphone technologies such as sensor-based "simultaneous localization and mapping" (SLAM), 3D rendering, and camera capabilities have made augmented reality accessible to most consumers with better applications (Pangilinan et al. 2019).

Virtual reality, typically called as VR, is a computerized simulation of a new environment with visuals and interactions through a head-mounted device and controls. Vision, audio, and haptic feedback create experiences that feel like real. Virtual reality replaces physical reality with computer-generated content and adds the core capability of simulation in addition to AR (Porter and Heppelmann 2017). VR spectrum provides several usage patterns based on immersion and interactivity. Web browser-based non-immersive, noninteractive simple applications such as consumption of 360-degree photos and videos are at the lower end of the spectrum. At the same time, head-mounted device (HMD) based experiences with controllers and 6° of freedom provide complete immersion and real-time interactive experiences. The hardware requirements

Immersive Visualizations Using Augmented Reality and Virtual Reality, Fig. 1 Reality-virtuality continuum as a function of immersion (Milgram et al. 1995)

for these experiences vary based on their complexity and application (Pangilinan et al. 2019).

Mixed reality, typically known as MR, uses a combination of augmented and virtual reality to create engaging experiences. The extended reality, typically known as XR, is an umbrella term that covers augmented, virtual, and mixed reality. It also encompasses other supporting technologies such as AI (Artificial Intelligence), 5G, IoT (Internet of Things) to create engaging and interactive applications (Pangilinan et al. 2019).

AR and VR have wide-ranging applications across industries. Depending on the need for interactivity, immersion, and visualization, the applications make use of AR or VR appropriately. Enterprise sectors such as education, manufacturing, healthcare, military, real estate have seen early adoption of AR and VR for applications such as simulated walkthroughs, remote surgeries, combat training, employee training, and more (Carmigniani et al. 2011; Sicaru et al. 2017). Consumer segments such as retail, e-commerce, education, gaming, entertainment, and tourism also make use of AR and VR for applications such as virtual try-on for products (Bonetti et al. 2018, interactive books, interactive advertisements, immersive videos, virtual tours of famous places (Huang et al. 2016), and 3D interactive lessons Kosa and Uysal 2019).

Since the advent of Internet and mobile penetration, the amount of data and information processed in every enterprise and consumer application have grown exponentially. This situation poses significant challenges for users to make use of data and information for activities such as decision making, gaining insights, learning effectively, and collaborating. One of the critical elements that makes data accessible and usable for users is the visualization of it. The primary objective of data and information visualization is to facilitate learning and decision-making of users across the personal and organizational spectrum (Schintler and McNeely 2020).

As the complexity and volume of the information and data are increasing exponentially, the traditional methods of 2D and 3D visualizations on flat screens of computers or phones are not sufficient enough. Hence, emerging technologies such as AR and VR are being explored by researchers and businesses.

Need for Immersive Visualization

There are various reasons data visualization is increasingly becoming more critical in recent times. With growing complexity and volume of data, aggregation and creating insightful or delightful experiences is a significant challenge. The purpose of visualization varies based on applications, and some of the objectives are facilitating higher learning, speedier decision making, and keeping the user at the center of data and insights. This process must seamlessly work for general as well as professional users (Schintler and McNeely 2020).

Decision-making process analyses data to extract patterns and facilitate the discovery of knowledge or insights. Reducing the complexity of data to discover trends and anomalies lead to accelerated and more accurate decision making. Visual data mining techniques use human visual perception to gain insights from patterns. Immersive technologies assist significantly in this entire process (Moloney et al. 2018).

Scientific visualizations play an essential role in facilitating learning and information sharing among researchers, businesses, and government organizations. Applications such as stocks analysis or sports analytics are usually multidimensional and hence difficult to visualize on existing visualization technologies such as 2D or 3D. Entertainment and gaming applications require greater interactivity to enjoy the overall experience. Industrial applications, such as healthcare training or enterprise training, require a sense of physical presence to be more productive (Sicat et al. 2018). Due to these several complex situations, immersive visualizations become a tool of preference for personal and enterprise use.

Augmented and virtual reality have been extended from the original continuum to the multidimensional realm. Now it covers a sense of presence, level of interactivity, and the mechanism to achieve these through the embodiment of suitable devices (Flavián et al. 2019). In other words, the primary characteristics of immersive technologies such as fidelity with spatial, visual,

and aural senses of humans make it perfectly suitable for complex data and information visualization (Moloney et al. 2018).

Applications of AR and VR for Immersive Visualizations

This section presents a summary of applications from various industries which use immersive visualizations through AR and VR to facilitate decision making, learning, or experiences effectively.

Retail

Virtual Try-On of clothing or accessories through augmented reality is picking up among consumers as well as retailers. An in-store augmented mirror setup provides users with a digital catalogue to try-on for clothing and accessories. The proposed AR application gives an enhanced shopping experience compared to the physical model leading to higher customer satisfaction due to the speedier decision-making process for shopping. As a result, physical retail stores can provide greater choice to users similar to online methods and augment it with a sense of a physical presence (Bonetti et al. 2018).

A study was conducted that ingested data from neuro-scientific tools such as tracking eye movements, storing navigation, and selecting the brands in a virtual supermarket, performing data analysis, and thereby gaining insights about consumer choices, customer experience, and shopping behavior in a store. Qualitative analysis was also used to compare the choices of consumers and the subsequent outcomes and sales. The overall suggestions correlated high attention devoted to a brand and slow eye movements (between brands), to additional brand purchases within the category. The outcome of the results meant that that the additional brand choices drive the time buyers spent on the first choice. Hence, less time available for the first selection leads to additional purchases within the product category and increased sales (Bigne et al. 2015). This is a good use-case of how a VR environment was used to identify retail consumers' behaviors to improve product placements and, hence, increase sales.

Manufacturing/Production

The training and manufacturing process of assembling desktop computers is enhanced with AR to convert instructions manual into a step-by-step visual guide. The proposed AR app is a simplified process to follow for new employees without losing the task's context. The clarity of instructions leads to reduced errors and lesser training costs incurred by the organizations. Thus, productivity is higher, and product quality is also enhanced (Osborne and Mavers 2019).

By combining the manufacturing industry with VR technology, enterprises can remain competitive by utilizing quality inputs in new product developments. In manufacturing enterprises, by its visualization and immersive experience, VR helps in aggregating relevant information and enables faster decision-making during the product development processes. A thorough analysis shows the increasing use of VR technologies and further research being conducted to increase the practical use of VR technologies (Choi et al. 2015).

Education

A virtual tour of heritage locations provides immersive history and cultural experiences to students. In one of the examples, a 360-degree virtual simulation is created at the historical center of the city of Rethymno in Greece to teach ancient history and culture. A virtual reality application gives learners a higher attention span due to a virtual environment free of distractions. The additional sense of physical presence helps to facilitate greater understanding and engagement to the learners. The level of interactivity fostered through the VR application evokes higher interest in learners than just consuming content over the screen (Argyriou et al. 2020).

Real Estate

4D CAD models and immersive visualizations are used in structural steel framing operations to showcase the design and construction process to all stakeholders for approvals and updates.

Through effective visualizations, construction processes and operations are streamlined processes. The outcome means the decision-making process is effective due to lesser ambiguity reduced errors and greater participation and engagement of all stakeholders (Kamat et al. 2010).

Healthcare

Patient care and training in the poststroke phase are one of the healthcare use cases using immersive technologies. The rehabilitation of body-part functioning (such as hands) is enhanced through AR assisted devices for common tasks such as reaching out and grasping objects. The approach involving AR helps give haptic feedback, and the interactivity helps in accelerating the patients' rehabilitation process. The process is highly scalable due to the re-use of the virtual environment resulting in cost saving for patient care. As AR systems are easy to set up, the manual operations effort is reduced (Xun et al. 2005) (Fig. 2).

The surgical workplace is transforming with the help of emerging technologies like VR and AR. VR applications play an important role in healthcare by enhancing the medical use of data such as anatomy, intraoperative surgery, or postoperative rehabilitation. This process is accelerated by an increase in the availability and speed of VR hardware and a reduction in price (Khor et al. 2016) (Fig. 3).

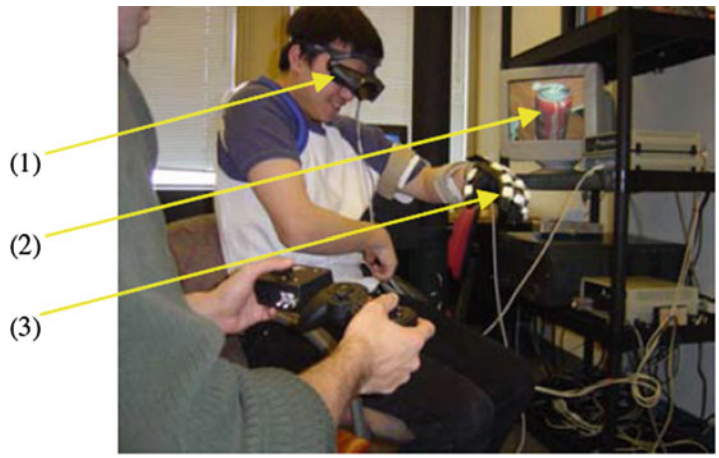
Tourism

Tourist destination marketing is using virtual reality to spread interesting information among customers. Creating interactive and informative virtual worlds to market tourist destinations is attracting customers. This method of using immersive visualizations provides higher consumer engagement and more credible marketing efforts resulting in less ambiguity for customers. Hence, marketers receive a higher satisfaction rate from their consumers as the immersive visualization of destination gives a more realistic look and feel of what to expect. The outcome is that the customers make their decisions faster (Huang et al. 2016; Huang and Liao 2015).

Augmented reality applications are enhancing the overall tourism experience by providing more context-specific information in a museum. The tourists could use their smartphone camera and augmented reality application to know interesting information such as history and facts about each article presented in a museum. This experience significantly adds value to the tourist's knowledge in a very engaging way without losing the context and language barriers in a foreign location (Yung and Catheryn 2019).

Wellness

Virtual reality and interactive, immersive games are being used to increase mindfulness. Its applications include therapy for pain management and mental wellbeing. The VR approach offers



Immersive Visualizations Using Augmented Reality and Virtual Reality,
Fig. 2 Rehabilitation process of the stroke patients using AR apps. (Xun et al. 2005)

Immersive Visualizations Using Augmented Reality and Virtual Reality, Fig. 3 Surgeons using Google Glass in Operating theatres. (Khor et al. 2016)

contextual visualizations leading to lower mental stress and perceived pain. The immersive approach avoids distractions from the real-world to assist in the healing process. This ultimately leads to higher satisfaction among patients and speedier recovery (Kosa and Uysal 2018).

Journalism

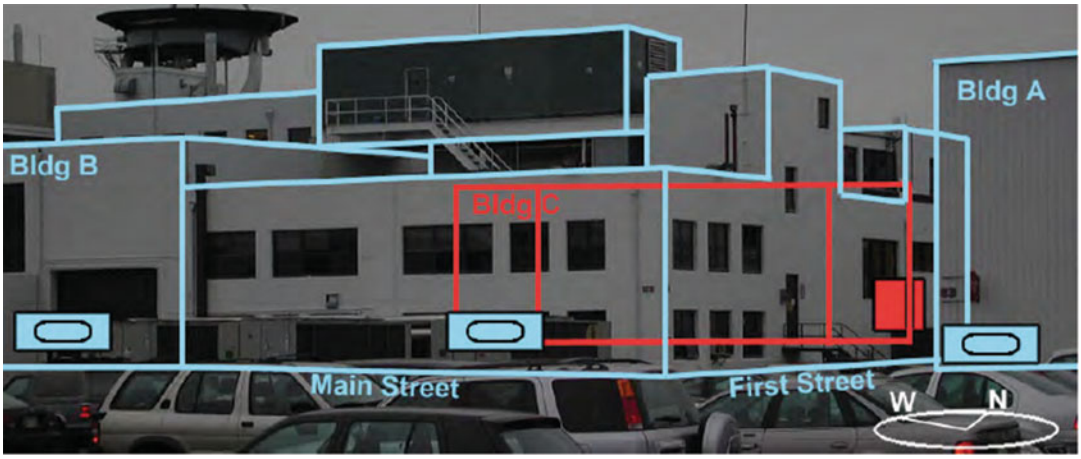
Interactive prints and immersive storytelling are revolutionizing the journalism industry. Augmenting the print media formats with digital content through AR and immersive storytelling makes news more effective and engaging. The immersive storytelling approach makes for more effective storytelling (via interactive media). The digital augmentation enhances the value of existing media such as print to make it more relevant for the users. It enables the users to get an easier transition from the existing medium to a new medium without losing context. Some of the limitations in this approach are lack of hardware availability, lack of tools for content creation, and lack of awareness among consumers (Pavlik and Bridges 2013).

Immersive storytelling is also experimented through virtual reality by many leading broadcasting and publishing companies such as *The New York Times* to deliver a first-person account of refugees during displacement due to crisis. These short experiences put a consumer in the middle of the action through 360-degree videos and evoke a strong sense of reality and empathy. The use of VR transforms the news from an account of data and information to an experience that heightened the learning as well as entertainment of the consumer. One of the limitations in this approach is shorter usage span of virtual reality due to headset issues, hence short, and bite-sized documentaries are popularly used for such experiences (Sirkkunen and Uskali 2016).

Defense

Military training uses virtual reality to simulate battleground and teach strategic tactics through interactive training for the forces. The VR simulations enhance both the navigation and coordination capabilities among soldiers. This method provides a more accurate representation of war scenarios and difficult situations than usual mediums due to its immersive environment and interactivity. The immersive simulations provide scalability and flexibility in training content (Livingston et al. 2011) (Fig. 4).

Augmented reality is used as a handy tool to disseminate real-time context-aware information in a military operation. This objective can be achieved through a head-mounted AR glass or a handheld device such as a smartphone. The usage of AR also helps in getting remote assistance or recreation of a specific environment, such as a demolished structure. It helps understand minor and vital details about the actual environment and make rapid decisions in combat situations. Navigation information is also delivered on an AR headset to guide the personnel making the experience seamless (Dodevska et al. 2018).



Immersive Visualizations Using Augmented Reality and Virtual Reality, Fig. 4 Military training simulation example, using Virtual Reality

Limitations

There are various technical as well as business challenges in implementing immersive visualizations using AR and VR. VR experiences are limited by the quality of the headset, quality of software applications, and interactivity issues. Standalone wireless headset suffers due to processing capability, weight, field-of-view, and battery life. High-end PC based VR headsets are difficult to set up and expensive. If not designed well, software applications can deliver a bad experience to users, including motion sickness. Interactivity is currently limited to the use of controllers and hand gestures, which are still evolving. Augmented reality experiences on AR glasses are limited by the design, size, weight, battery, and field of view of the headset. Smartphone-based AR experiences are widely used now. However, they do not provide rich, immersive experiences and interactivity. They suffer from issues such as dependency on a specific smartphone model, GPU capabilities of smartphone and smartphone hardware such as camera and display. Business limitations such as awareness about the technology, cost of adopting the technology, and consumer readiness are being researched for AR and VR implementation. Lack of maturity of the eco-system, such as availability of suitable hardware, software, and content, is also a challenge (Chandra and Kumar 2018; Leovaridis and Bahnă 2017; Porter and Heppelmann 2017).

Conclusion

Various applications of AR and VR provide better visualizations over traditional methods resulting in better decision making, cost savings for organizations, enhanced experiences for consumers, and many more. Immersive products provide an edge over the competition for businesses and enhance brand value, better stakeholder communication, and higher client satisfaction. At times it also facilitates cost reduction in specific scenarios. Though AR and VR as technology are beneficial and advancing at a rapid pace, there are some short-term challenges in implementing immersive visualizations. To overcome these challenges and make immersive visualizations effective, solution providers need to design products and services which provide the appropriate level of presence, interactivity, and immersion based on application. The human-centered design needs to be adapted for more human senses as AR and VR can make use of visual, aural, and spatial dimensions.

Incremental Games

Mikhail Fiadotau
Centre of Excellence in Media Innovation and Digital Culture (MEDIT), Tallinn University, Tallinn, Estonia

Synonyms

Clicker game; Idle game

Definitions

Incremental game (otherwise known as idle game or clicker game) is a resource management game whose core mechanic consists of repeatedly performing a simple action, such as clicking a button, in order to gain currency. A prominent feature of incremental games is that after an initial time investment by the player, automated currency production is usually unlocked, allowing the game to continue in the background with little player interaction for extended periods of time.

Introduction

The year 2013 saw the rise to prominence of several early incremental games such as *Cookie Clicker*, *Candy Box!*, and *A Dark Room*. While displaying significant variation in terms of their aesthetics and storylines, all three relied on the same core mechanic of continuously clicking to accumulate currency (cookies, candies, or wood in the respective examples) in order to exchange it for other game objects and resources. The speed of accumulation would gradually increase and after a few initial interactions with the game, the accumulation process would become automated, enabling the player to leave the game running in the background and return to it occasionally to click for additional currency or spend it on upgrades, artifacts, and access to new types of resources (Deterding 2016).

These examples have inspired numerous subsequent games utilizing a similar dynamic, including *Clicker Heroes* (2014), *Plantera* (2016), and the educational *Rebuild the Universe* (2015). In the span of a few years, incremental games have become an established genre, even as multiple terms continue to be used to denote this genre, focusing on different aspects of it: incremental game, idle game, clicker game. Explaining the rising popularity of the genre, game critic Nathan Grayson pointed out that due to not demanding constant attention from the player, incremental games were easy to integrate into a daily routine and could be played even at one's workplace (Grayson 2015).

Origins

The idea of a game playing itself goes back to at least J.H. Conway's *Life* (1970), where the player sets up the initial configuration of the game in the beginning, but has no influence over the subsequent progression of the game (Björk and Juul 2012). More recently, *Godville* (2010) was a notable game to have entirely optional player interaction, casting the player as a god overseeing a world in which the nonplayer controlled hero adventures.

In the same year, *Cow Clicker*, a game that completely relied on repetitive clicking to progress was released by American researcher and game designer Ian Bogost. *Cow Clicker* is a Facebook game with a minimalist mechanic: the player clicks on a cow in order to obtain currency (clicks); however, they need to either wait for 6 h to click again or make a microtransaction to skip the waiting time. Bogost explained *Cow Clicker* as a satire of contemporary social games, which rely on the freemium distribution model and impose various limitations on the player in order to encourage them to make in-game purchases (Bogost 2012).

Despite its stripped-down gameplay and satirical nature, *Cow Clicker* gained significant popularity and inspired a number of similar games. Most notably, it became the inspiration for aniwey's *Candy Box!* and Julien Thiennot's

Cookie Clicker, which were among the earliest incremental games proper.

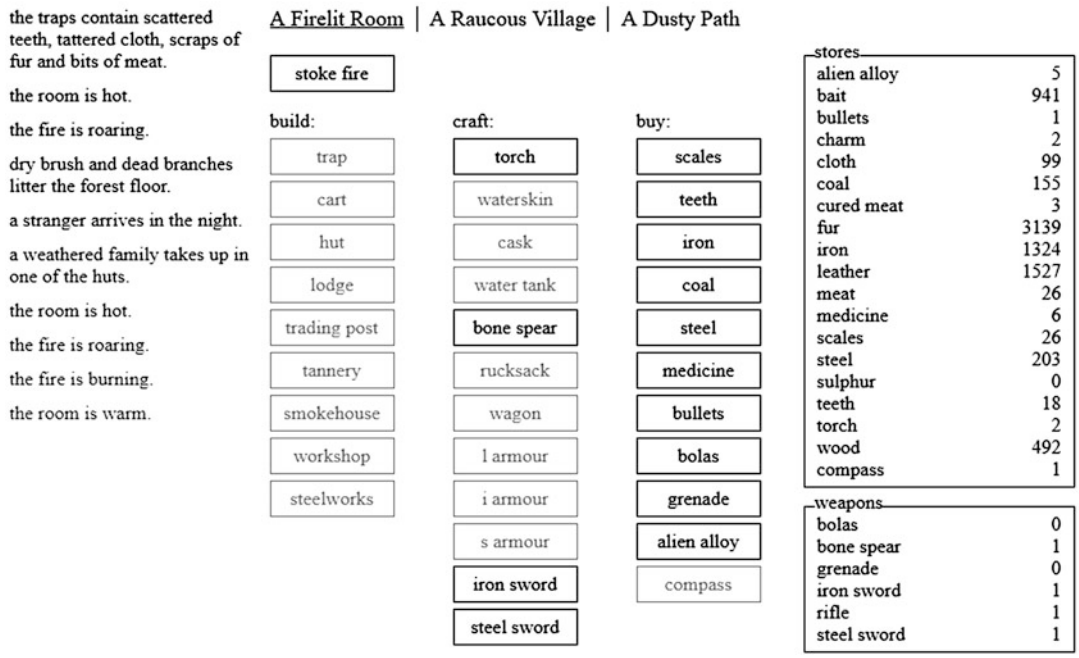
Structure

Incremental games share the following key features:

1. Their core dynamic is based on accumulating currency.
2. Initially, this is achieved by the player performing a certain repetitive action such as clicking.
3. After some player input, currency accumulation can be automated, enabling the game to "play itself" in between interactions with the player.
4. The game gradually increases in complexity, uncovering new features, resources, items, and locations.
5. This new content usually has to be unlocked by the player as it is not enabled automatically. Unlocking new content requires increasing amounts of currency.

This logic of increasing complexity means that beyond the core dynamic of incremental resource accumulation, idle games can rely on elements of different genres. For example, in *Candy Box!* and its sequel *Candy Box 2* the main currencies (candy and lollipops) are mainly used to unlock new locations and obtain items such as weapons and armor, which enables the player character to go on adventures and complete quests. This makes *Candy Box!* fundamentally a role-playing game. By contrast, *A Dark Room* features a much bigger variety of resources (wood, fur, cloth, meat, steel, coal, medicine, etc.) and mainly revolves around managing and defending a growing village, making it a strategy game (Fig. 1).

Some idle games, such as *Godville*, require no input from the player whatsoever. These are known as zero-player games, although it needs to be pointed out that just as not all incremental



Incremental Games, Fig. 1 Resource management in *A Dark Room*

games are zero-player, neither are all zero-player games incremental.

Significance

Incremental games "break with conventions and expectations regarding games" (Deterding 2016) and have led scholars to question existing definitions of video games, as these often revolve around player agency, which is limited in idle games (Khaliq and Purkiss 2015). Zero-player games in particular are problematic due to the absence of an obvious player figure (Ruffino 2016), leading Björk and Juul (2012) to argue that the idea of a game as something actively played by at least one human does not do justice to the complexity of both the notions of "game" and "player." In Deterding's (2016) words, while incremental games "started as an artistic inversion of game design conventions to demarcate the boundary of 'real' games," they ended up "expanding rather than delimiting the category."

The popularity of incremental games also reflects the evolution of the ways we use media. By allowing players to attend to other tasks while the game plays itself, incremental games accommodate the increasingly prevalent behavior of media multitasking (Bardhi et al. 2010). While incessant alternation between a variety of information sources was already conceptualized by Toffler as "blip-culture" (Toffler 1981), the advent of broadband Internet and powerful computers has furthered this process, leading to even shorter attention spans and more diverse media competing for audience attention. Incremental games, due to not demanding much player commitment while providing a sense of progress, fit this paradigm well.

Independent game

Definition

An indie game is a game created by an independent team of developers, typically with limited resources, without a publisher or with no significant involvement in the artistic process on the publisher's part. Indie games are often experimental and/or employ a retro aesthetic. While the label is usually associated with digital games, it can also apply to analog (e.g., tabletop) games.

Overview

The term "indie game" became prominent in the mid-2000s (Garda and Grabarczyk 2016), although the concept of "indie" itself dates back to the 1980s (Hesmondhalgh 1999). "Indie" is a short form for "independent," indicating creative autonomy which indie producers are deemed to possess. While the concept originated in the music industry (Hesmondhalgh 1999), it gradually expanded to other spheres such as cinema (Newman 2009), fashion (Hauge and Hracs 2010), and, eventually, games.

The diverse indie media form a loose continuum of "indie culture," which "derives its identity from challenging the mainstream" (Newman 2009: 16) and generally embraces lo-fi aesthetics (Lipkin 2012). However, there is little systematic interaction between the different media within the spectrum of indie culture, with each of them having its own conventions and audiences which do not necessarily overlap.

In case of indie games, their rhetorical opposition to mainstream gaming has resulted in a tendency to use pixelated retro graphics and chiptune music evoking the look and feel of old video games. Notable indie games such as *Cave Story* (2005), *Fez* (2012), *Hotline Miami* (2012), and *Stardew Valley* (2016) can all be seen as homages to "classic" video games of the 1980s and early 1990s, even as they subvert or enrich the conventions of older games. Even the indie titles that do not directly utilize retro aesthetics tend to have a distinct visual style which looks minimalist compared to the hyperrealistic graphics of most mainstream games (at least in the West). This is the case for hand-painted platformer *Braid* (2008); the grainy, black-and-white *Limbo* (2010); the voxel-based 3D sandbox *Minecraft* (2011); and the lo-fi, full-motion video-based *Her Story* (2015). This approach to visual and sound design serves both a rhetorical and a practical function. On the one hand, it "is meant to invoke a type of authenticity <...> that marks it as distinct from the alleged realism" of mainstream games (Juul 2014); on the other hand, it enables indie developers to deal creatively with their limited budgets and skills (Lipkin 2012) (Fig. 1).

In addition to the purely aesthetic aspect, indie games also differ from mainstream big-budget titles insofar as the former are more open to experimentation and "aim to push the envelope of game design" (O'Donnell 2012). This experimentation can manifest in using innovative mechanics and having unusual plotlines and settings. For example, *Gods Will Be Watching* (2014) features an unlikely combination of point-and-click adventure with resource management (the resources being variables relating to the physical and mental well-being of its characters). *Braid* enriches the traditional puzzle platformer gameplay by adding the ability to rewind time; it is also revealed at the end that the hero's quest was a metaphor for the invention of the atomic bomb (Jagoda 2013). Text-based indie games by such authors as Anna Anthropy and Porpentine have dealt with queer identities and gender dysphoria, topics not commonly addressed by mainstream games. *That Dragon, Cancer* (2014) is an autobiographical indie game designed by Ryan and Amy Green to communicate their experience of caring for, and ultimately losing, a child diagnosed with cancer. These examples show the wide thematic range of indie gaming (Fig. 2).

Evolution of the Concept

When "indie games" first became an established term in the mid-2000s, it was often conceptualized in terms of the parameters of production such as budget, team size, revenue, and distribution model. Consider one of the early definitions of indie games in an academic paper: "Indie games are video games that have a small or non-existent budget and are often primarily available online or through friend-to-friend sharing" (El-Sattar

Indie Game, Fig. 1 Fez (2012) utilizes the retro platformer aesthetic, but subverts it by adding a third dimension

Indie Game, Fig. 2 Anna Anthropy's Dys4ia (2012) addresses an issue not commonly seen in digital games: gender dysphoria

2008). These definitions overlooked the temporal aspect of indie games: while "independent games" had existed for decades, designed by students in computer labs and bedroom developers in their homes, the narrower label "indie" is overwhelmingly used to refer to games developed in the twenty-first century (Garda and Grabarczyk 2016).

The circumstances of production are thus less central to defining indie games than the particular temporal and cultural context of their origin. The emergence of indie games was made possible by the availability of consumer-grade game engines such as *Game Maker*, *RPG Maker*, and *Unity* (Garda and Grabarczyk 2016), as well as the rise of digital distribution enabled by widespread access to broadband Internet and the shift to Web 2.0 (Parker 2013).

Moreover, as major corporate players, recognizing the market potential of indie gaming, started to publish games by indie studios and as crowdfunding platforms made it possible for indie developers to command large budgets, the understanding of what constitutes "indie" has also begun to shift. While it is still generally recognized that an indie game has to be developed by a small studio (which may, however, operate on a large budget and work with a major publisher), much of the focus is now on a general "indie sensibility" and indie aesthetic (Juul 2014). The shift to digital distribution platforms such as

Steam, where indie games and big-budget mainstream titles coexist within a single ecosystem, has rendered the circumstances of production nearly invisible, while highlighting the aesthetic feel and gameplay features which set indie games apart. The notion of an indie game was nebulous to begin with (Parker 2013), but now indie gaming seems to have mirrored the development trajectory of earlier indie media such as music and film: a shift from a movement characterized by relatively authentic opposition toward the mainstream to an aestheticized label largely incorporated into the very mainstream industry it once set out to challenge (Lipkin 2012).

Indigenous Knowledge for Mental Health, Data Visualization

Hooria Hajiyan, Shawkh Ibne Rashid and Mehran Ebrahimi
Faculty of Science, Ontario Tech University, Oshawa, ON, Canada

Synonyms

Data Visualization of Mental Health Issues; Mental Health of Indigenous Peoples

Definition

Indigenous is a common term used for First Nations, Inuit, and Métis in Canada. Indigenous peoples of Canada suffer from mental health issues more than their non-Indigenous counterparts. According to history, the delocalization of these people to remote places made them live independently, which strained their mental health (Kunitz 1996). Identifying the causes of mental health issues in Indigenous peoples and mitigating them is of dire need. One difficulty with understanding the main reasons for these mental issues is the existence of multiple contributing factors. These include different barriers that Indigenous peoples face in accessing healthcare because of colonization, cultural discontinuity, and racism and residential schools. On the other hand, Indigenous knowledge is still the main remedy for such kinds of mental problems in Indigenous communities. Representing the common mental problems between different groups of Indigenous peoples and the traditional way of life as a remedy for each specific group remains a challenge. Data visualization has evolved to create visual representations of data to help people quickly assimilate large amounts of information. Hence, data visualization can help to identify and assess factors relating to mental issues in different groups of Indigenous peoples.

Introduction

The significant mismatch between their traditional way of living and the current capitalism-based lifestyle plays a part in the increasing mental health cases among the Indigenous peoples. Surveys conducted on this issue show the deteriorating picture in terms of mental health in this community compared to their non-Indigenous peers (Nation n.d. 2010). There are various causes which have been linked to the deteriorating mental health condition of the Indigenous people. Cultural discontinuity, colonization, and obstacles in accessing healthcare all can contribute to this condition.

Data Visualization

There have been various research surveys and studies conducted on the mental health of Indigenous people. These studies have provided a comparison between Indigenous peoples' mental health and their non-Indigenous counterparts' mental health. We can also see a gender-based comparison from some of the surveys. Figures 1 and 2 (Nation n.d. 2010) show the gender-wise comparison in Indigenous peoples. In Fig.1, we can observe that females have more suicidal thoughts than males and this is much smaller in non-Indigenous people than Indigenous people. We can also observe a higher suicide rate in Indigenous peoples in Canada, specifically among First Nations, compared to the non-Indigenous peoples (see Fig. 2), where the rate is higher for males than females.

Figure 3 (Nasir et al. 2018) represents the presence of common mental disorders among Indigenous Australians compared to the general population of Australia. We can see a similar trend of high mental health issues in the Indigenous population of Australia compared to the non-Indigenous people. In this Figure, the superscripts are indicated as the total Indigenous Australians % / total National Survey of Mental Health and Wellbeing, (NSMHWB) %.

Barriers in Accessing Healthcare

Barriers in accessing healthcare can be defined into three different categories, Proximal, Intermediate, and Distal barriers. Proximal barriers include geographical living places, lack of local educational institutions, and lack of presence of healthcare professionals that can negatively affect Indigenous peoples accessing primary healthcare (Nguyen et al. 2020). Intermediate barriers stem from a lack of employment opportunities and inadequate income. The distal barrier comprises colonialism, racism, and social exclusion. This hampers the involvement of Indigenous peoples in policymaking and accessing the proper mental healthcare (Nguyen et al. 2020). The effects of Colonization, Cultural Discontinuity, and Racism

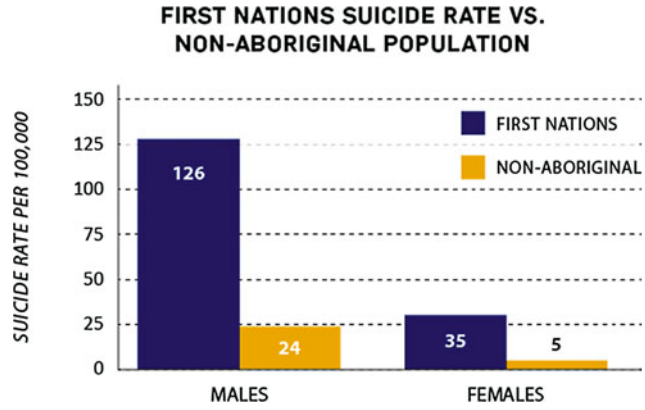
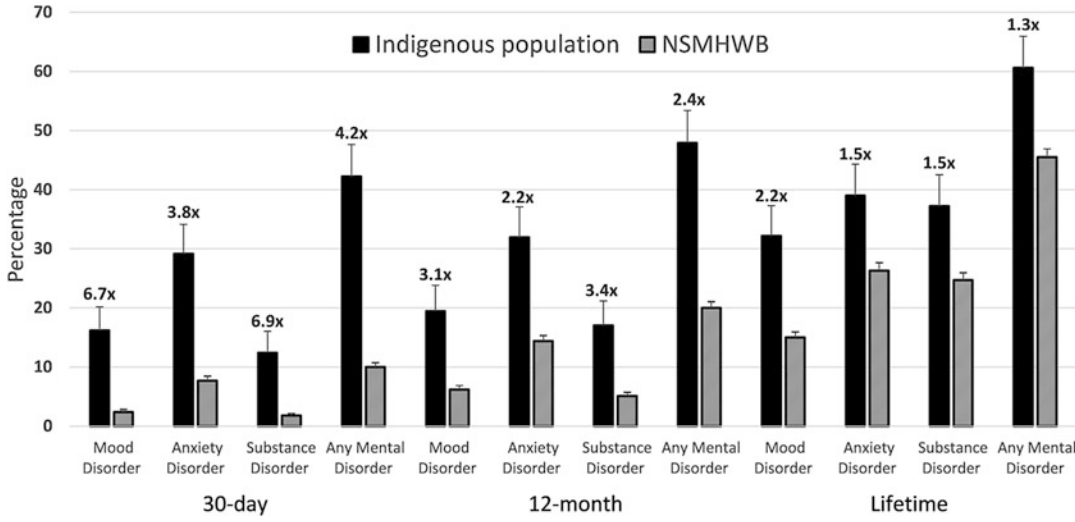
Indigenous Knowledge for Mental Health, Data Visualization, Fig. 2 Comparison of suicide rate between First Nations and non-Indigenous people





Indigenous Knowledge for Mental Health, Data Visualization, Fig. 3 Standardized 30-day, 12-month, and lifetime prevalence of frequent mental disorders among Indigenous Australians compared with the general Australian population

and Residential Schools are still the most significant barriers that indigenous peoples are facing toward mental healthcare in Canada.

Colonization

The colonization of Indigenous peoples in Canada and its impact on their identities are significant when discussing mental health issues of the Indigenous community (Stout and Kipling 2003). The mental well-being and recovery of Indigenous peoples in Canada have always been tied to history, mainly about dislocation from their traditional lands and its consequences (Lavallee and Poole 2010). Several studies show how colonization impacted all aspects of Indigenous peoples' lives, including health, tradition, access to services, and equity, among others (Ristock et al. 2019; MacDonald and Steenbeek 2015). The colonization of Indigenous peoples in Canada and the historical impacts on their health, economic, and cultural experiences are well documented (Ristock et al. 2019). The results show that the source of low levels of mental well-being among indigenous peoples in Canada stems from the loss of traditional practices, breakdown of the family unit, and disconnection from the traditional culture.

Cultural Discontinuity

The cycles of family disruption, colonization, dislocation from traditional lands, and outlawing of spiritual practices among Indigenous peoples have led to many health and social inequities (Reading and Wien 2009; Halseth 2013). Rates of suicide, depression, and substance abuse are significantly higher in many Indigenous communities than in the general population (Lafrance et al. 2008). Colonization did not end with the creation of the new nation-state. In the past, Canadian government policies, including forced relocation of Indigenous peoples to remote regions, residential schools, and bureaucratic control, have continued to destroy Indigenous cultures (Kirmayer et al. 2007). This cultural discontinuity has been linked to a high rate of depression, alcoholism, suicide, and violence in many communities, with the most profound impact on youth. We see these traits in Indigenous peoples as they do not recognize the system compatible with their thinking (Firestone et al. 2015).

Racism and Residential Schools

The decentralization of Indigenous peoples from their natural habitats to remote locations and random social groupings forced them to adopt new ways of life. Relocating them was a part of the political and economic agenda. These policies served the non-Indigenous people with their interests, and explicit and precise forms of racism sustained this. These suppression efforts and harsh policies resulted from the thought that differentiated Indigenous culture as primitive and their people as uncivilized (Kirmayer et al. 2000). This prevented these people from practicing their religion and culture. They were even not permitted to participate in the democratic government. Therefore, as a means of getting rid of their culture and religion, residential schools were formed. Cultural assimilations were imposed on the Indigenous children by making it mandatory for them to get admitted to these schools. These all played a negative role in the mental well-being of Indigenous peoples and their children specifically (Nelson and Wilson 2017).

Common Mental Issues among Indigenous Peoples in Canada

First Nations adults experience a disproportionate burden of mental well-being and addictions. A study conducted in Hamilton on an urban First Nations population shows that among the 554 First Nations adults who participated in the study, 42% had been told by a healthcare worker that they had psychological and mental health disorders. Furthermore, 39% of them were suffering from high rates of depression, 34% had Post-Traumatic Stress Disorder (PTSD), 41% had suicide ideation, and 51% of attempts were reported (Firestone et al. 2015). PTSD might be linked to residential school attendants, abuse and family violence, family disruption by child protection services, and transgenerational trauma related to these, and other impacts of colonization (Menzies 2010; Corrado and Cohen 2003).

Another study has pointed out the high rate of mental disorders among Indigenous peoples (Tait et al. 2017), which states that suicide is a concern for many Indigenous communities in Canada. The rate of suicide among Indigenous peoples in Canada is higher than the national average. According to 2000 reports from the Canadian Institute of Health, suicides among First Nations youth aged 15 to 24 were about five to six times higher than non-Indigenous youth in Canada (Hossain and Lamb 2019). Indigenous peoples face a range of mental health issues at a higher rate than their non-Indigenous communities, and their life expectancy is also shorter (Frideres 1998; Waldram et al. 2006). The cause of this can be traced to higher rates of death among accidental death in young people and suicide. High levels of mental health problems have been documented in Indigenous communities (Nation n.d. 2010; Waldram et al. 2006). Mental health issues are directly affecting the social life and economic state of these people. The high rate of suicide, alcoholism, and violence can be both causes and effects of mental health problems. Suicide is one of the most dramatic indicators of distress in Indigenous populations. Epidemiological surveys undertaken on different communities of Indigenous peoples have pointed out the elevated rates of suicide among First Nations, Inuit, and Métis communities (Frideres 1998). These studies show that young people have a higher tendency toward suicide and attempted suicide. The results prove that assault on cultural identity besides low self-esteem is the main factor of this.

Indigenous Knowledge for Mental Health

Some remedies to these mental issues considering the traditional Indigenous way of life include Identity, Cultural Attachments, Languages, Community, Demographics, and Physical Activities and Games (Danto and Walsh 2017).

Identity

Natural healing for Indigenous peoples must include work around identity. The cultural identity of these people is one of the primary aspects that colonization has attacked and still affects them (Danto and Walsh 2017). The assault on cultural identity has played a significant role in the ill health of Indigenous peoples, and the spirit has been wounded. In that case, healing activities need to include rebuilding their individual and collective identity. This healing activity consists of a spiritual understanding of the individual and collaborative Indigenous culture.

Cultural Attachments

There is a relationship between cultural attachment and mental health among Indigenous peoples in Canada. Cultural attachment is assessed by involvement in traditional activities and Indigenous languages (Hossain and Lamb 2019). In addition, culture includes notions of how people react to situations, family patterns, and social interactions. Therefore, a new generation of practitioners is emerging who can combine local knowledge about health and healing with the most valuable aspects of psychology.

Language

Language is a primary conveyor of culture and people are most readily connected to their emotions and thoughts in their first language. Behavioral health scientists are assigning high importance to understanding a group's culture and traits in terms of treating mental health problems. On the other hand, language is one of the most vital components of culture and thus can impose great possibilities in understanding the psychology of a group of people. Various studies have explored language through its relationship to other demographic and cultural variables (Gonzalez et al. 2017). Studying different components of Indigenous language and focusing on the impact that they can impose on the mental health of the Indigenous population can be a means of bolstering the mental stability of this community.

Community

Despite the failures of the deinstitutionalization era in Canada, the community remains a central concept in mental health policy, clinical practice, and research. The idea of "community" is present in mental health policy, research, and clinical practice

in Canada (Gonzalez et al. 2017). The concept of community in treating mental well-being problems has a long history in the West, including thoughts about healing communities. The healing power of social relationships and the health impacts of the social and physical environment were central to this perspective. The optimism behind this should turn us toward community-based mental health services (Kirmayer et al. 2000).

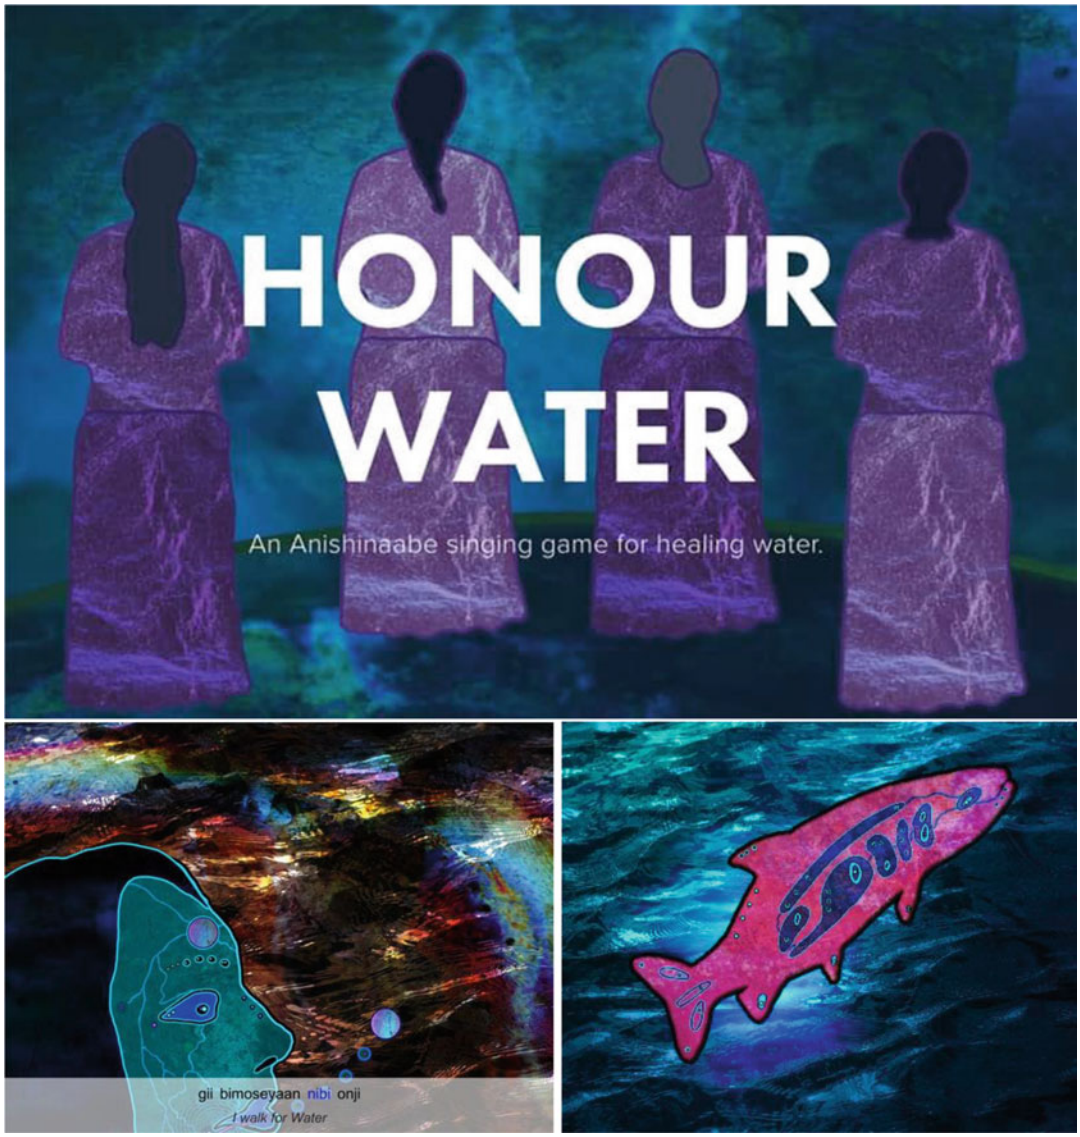
Demographics

When we address such critical issues as mental health, we should consider different needs and approaches for groups of people based on age, race, etc. For example, based on the references, there is a high rate of suicide among Indigenous youths, especially among First Nations, which is related to unemployment and economic issues (Tait et al. 2017; Hossain and Lamb 2019).

Physical Activities and Games

The physical activity program is the best way to understand Indigenous culture and identity. A high sense of belonging to the community and physical activity is associated with improved mental health and spiritual growth, specifically in older people (Bailey and McLaren 2005). Studies show that having the ability and motivation to belong in groups and doing physical activities with others contributed to the mental well-being of retirees (Bailey and McLaren 2005; Waldram et al. 2006). The sense of belonging may need to be facilitated to enhance mental well-being. The results indicate that higher levels of sense of belonging are related to lower depressive symptoms related to suicide ideation (Lavallée 2007). Traditional ways of hunting and gathering foods can help the Indigenous peoples improve their mental well-being. It is worth mentioning that some healing ceremonies can improve their mental well-being, including Pipe Ceremony, Wedding Ceremony, Naming Ceremony, Sweat Lodge, Full Moon, Pow Wow, and Smudging. One of the appropriate ways to increase self-esteem and happiness among children is by engaging them in games. It refers to common physical activities/games that Indigenous and non-Indigenous children can play together, which improves mental well-being in Indigenous children and introduce their culture to non-Indigenous peoples (Dubnewick et al. 2018). Community-based participatory research was conducted in 2018 (Dubnewick et al. 2018) to better understand how participation in traditional games can enhance the sport experiences, and further the mental well-being of Indigenous youth. Eight Indigenous youth (14–18 years) and 10 adults living in various communities in the Northwest Territories, Canada, participated in either a one-on-one interview or a group interview. Data were analyzed using an inductive content analysis approach, and findings suggest that participating in traditional games can enhance the sport experiences of Indigenous youth by (a) promoting cultural pride, (b) interacting with Elders, (c) supporting connection to the land, (d) developing personal characteristics, and (e) developing a foundation for movement. Participating in activities such as traditional games, which incorporate traditional ways and Indigenous values, may provide a unique opportunity to enhance the sport experiences of Indigenous youth. That being said, traditional games can provide Indigenous peoples with the opportunity to engage in sport within an environment that reflects their cultures (Heritage 2005). Traditional games, including Inuit games (e.g., two-foot high kick) and Dene games (e.g., stick pull), are strongly influenced by life on the land whereby such games optimize the endurance, strength, and agility that were, at one time, necessary for survival (Heine 2006, 2007). Traditional games were central to the lives of Indigenous peoples (Heine 2013).

However, with European colonization and the "broader assimilative agenda in Canada," there was an effort to eradicate the traditional sports and games of Indigenous peoples. More recently a number of computer game development companies have created new computer games while advocating for technology across the Indigenous world. For example, Honour Water is an Anishinaabe singing game for healing water which is developed by Pinnguaq, a Nunavut and British Columbia based corporation (see Fig. 4). At the root of their mission statement is the embracement of technology as a means of unifying and enabling both Indigenous and non-Indigenous cultures.



Indigenous Knowledge for Mental Health, Data Visualization, Fig. 4 Screenshots of the Honour Water game on App Store- Apple Inc. (Courtesy of Pinnguaq Technology Inc. Songs by Anishinaabe elders and Sharon Day sung by the Oshkii Giizhik Singers pass on teachings about water in Anishinaabemowin)

More research would be required to evaluate the success of such computer games towards this mission.

Conclusion

Colonization and relocation of Indigenous peoples in Canada to remote places affected different aspects of their lives such as language, culture, traditional activities, and mental well-being. Similar to Indigenous populations of other parts of the world, Indigenous peoples in Canada have suffered adversaries leading to a very different way of living. Declining population due to epidemics of infectious diseases, religious conversion, enforced colonization, and separation from family members have all played a part in the changed

lifestyle of Indigenous peoples. The traits and nature of Indigenous groups are different and should not be generalized in terms of understanding their culture to treat mental problems. This will help us to have a better understanding of their needs and thoughts. Equity of well-being for the Indigenous population is vital for constructing an equal and just society. To achieve this goal, an analysis of the history and its impact on the Indigenous mental well-being, such as the common mental issues and barriers to accessing healthcare, should be studied and visualized based on the main factors, including Colonization, Cultural Discontinuity, and Racism and Residential School. Indigenous knowledge is a way of understanding their needs and improving their mental health around Identity, Cultural Attachments, Languages, Community, Demographics, and Physical Activities.

Indigenous Language Revitalization with Stories and Games

Aref Abedjooy, Fatemeh Hirbodvash and Mehran Ebrahimi
Faculty of Science, Ontario Tech University, Oshawa, ON, Canada

Synonyms

First nations; Mobile applications; Revival of Indigenous languages

Definition

According to Statistics Canada, numerous Indigenous languages are spoken in Canada. However, the number of speakers of these languages is declining due to historical and social factors. Efforts are underway to recognize the importance, preservation, and revitalization of these languages. A careful evaluation of the related challenges, potential solutions, and benefits is essential.

Introduction

The technological revolution has transformed almost every aspect of life including novel educational systems. Digital language learning technology has revolutionized language learning within only a few decades and it leads to becoming a prominent mode to study and learn a new language. It is no longer necessary to browse through heavy bidirectional dictionaries and textbooks as a tool to learn a new language. The availability of language data, the increasing demand from language learners, and greater access to native language speakers have enabled many innovations in the fields of linguistics and language learning. However, it is far more recent to apply these resources and technologies to the Indigenous languages of people from around the world. Traditionally, language learning resources and technologies have been built mainly with the purpose of teaching language aimed at tourism, business, and employment. Indigenous language technologies, on the other hand, are primarily aimed at language documentation, revitalization, and reclamation. As a consequence, since Indigenous languages possess unique characteristics, the current language technologies and methods may not be directly applicable in this context as a straightforward process. Indigenous language technologies have received increased support in Canada over recent years. However, greater opportunities require more discussion about what these technologies can look like and how they will be implemented in practice (Brinklow et al. 2019).

Background

Individuals use language as a means of communication, education, social interaction, and development. That being said, language is also deeply related to identity, cultural heritage, tradition, and memory. Hence, when a language is lost, cultural heritage and identity are lost and may be lost forever or not be recoverable at all (Oladimeji et al. 2020). According to the United Nations Educational, Scientific and Cultural Organization

(UNESCO), it is estimated that at least 40% of 7000 languages used worldwide are at risk of extinction. The use of Indigenous languages in Canada has been suppressed for generations due to the history of restrictive colonial policies. Many Indigenous languages are presently endangered since most of them are not taught or used in schools, universities, industries, and business. The year 2019 was designated the international year of Indigenous languages by the United Nations, to emphasize the importance of revitalization of Indigenous languages at the regional, national, and international levels. In Canada, one of the items listed in the Truth and Reconciliation Commission's Call to Action was that the federal government should acknowledge Indigenous languages as an inherent right of Indigenous peoples and support to "preserve, revitalize and strengthen" these (Justice Laws 2019). In the 2016 census in Canada, nearly 70 Indigenous languages were reported. There are tens of thousands of speakers for several of these languages, while others have a few tens or hundreds of mostly elderly speakers (Anderson 2018). Thus, Indigenous languages can be said to be endangered. Based on 2016 statistics, 260,550 Indigenous peoples can speak an Indigenous language well enough to conduct a conversation (O'Donnell and Anderson 2017). On the other hand, Indigenous peoples' language and culture are dependent on each other since their cultures are rooted in oral traditions. By oral tradition, Indigenous peoples transmit their epic poems, prayers, speeches, spiritual teachings, songs, stories, and history. The oral tradition usually transfers culture from one generation to the next through elders or older people. The oral tradition makes the importance of maintaining and revitalizing Indigenous languages more apparent.

The study in this entry suggests a user-centered application for the Indigenous Education and Cultural Services at Ontario Tech University that supports Indigenous languages. Ontario Tech University is on the Traditional Territory of the Mississaugas of Scugog Island and the territory is covered by the Williams Treaties. The Mississaugas is one of the branches of the largest Indigenous groups in Canada which is known as the Ojibwa Nation. Around 1700, the Mississaugas of Scugog Island moved from their previous home north of Lake Huron into southern Ontario. The Ojibwe language is the most prevalent Indigenous language in the area, which serves as a focus of this study (O'Donnell and Anderson 2017).

The authors of this entry are not Indigenous peoples and acknowledge that they are not in a position to speak to the values or views of the Indigenous communities or their culture. This entry aims to offer a view of possible options for designing a mobile app for learning Indigenous languages. It is important to mention that elders can always provide more valuable guidance on how to meet the needs of their communities.

Literature Review

In 2019, Morgan Cassels and Chloe Farr published a review paper on mobile applications for Indigenous language (Cassels and Farr 2019). The authors discuss whether mobile apps can strengthen language revitalization efforts and debate the advantages and disadvantages of using apps as a medium for Indigenous language learning. Furthermore, 32 apps are examined and concluded that some apps focus on a specific goal or strategy while others offer a wide variety of different activities, such as stories and games. According to the authors, most Indigenous language apps provide users with a mixture of dictionary features, common phrases, vocabulary exercises, games, quizzes, and cultural content.

In another study, Oladosu Oladimeji et al. examine how technology can play a role in revitalizing culture and language in acute areas (Oladimeji et al. 2020). They notice that individuals must show interest in the language to learn it. A new way of learning the Yoruba language is presented by using mobile games to arouse the interest of students and thereby further promote and revitalize the Yoruba language and culture. A survey questionnaire was used by developers to assess the quality of the mobile application that was installed by participants who explored

the application. The games are ranked based on some metrics including extensibility, security, ease of use, and whether the user finds it interesting to learn Yoruba after playing it. According to their result, 76% of respondents found the game easy to use, 70% rated it as sufficiently extensible, and 90% found it gratifying to learn Yoruba after playing the game. It will be an entertaining and interesting method of motivating people to develop an interest in learning the native Indigenous language individually or in groups.

In a more recent work, the National Research Council of Canada (NRC) conducted a project known as "Indigenous Languages Technology (ILT)" (Kuhn et al. 2020). Phase I of this project allocated $6 million in funding by the Government of Canada in March 2017 and Phase II of the project is currently underway. The ILT's project aims to produce software that will facilitate Indigenous language preservation and revitalization efforts throughout Canada. The authors mention that several technologies were developed in response to community demands, and the project was split up into subprojects including text-based and speech-based components. The authors indicate that a significant challenge in their project was in building respectful relationships with communities.

Issues

Many institutional and societal factors have contributed to the decline of Indigenous languages in Canada, such as the development of residential schools and the Indian Act. Assimilation of colonial culture was the explicit purpose of Canada's residential school system. This aim was achieved if Indigenous language and culture were not taught to generations of Indigenous children. These schools housed children forcibly taken from their homes. If they spoke their mother tongue there, they were punished. Thus, generations of Indigenous peoples turned away from their heritage and language. In 1996, after over 150 years, these schools were fully closed. As a result of the residential school system, many Indigenous peoples may still feel a sense of shame to speak their language (Brinklow et al. 2019).

English and French are the two official languages of Canada. According to the 2016 census, it reported that more than 95% of employees used English or French at work regularly (Lepage and Corbeil 2017). Furthermore, English and French are used in schools, universities, business, etc., and can be considered the languages of success. By viewing this reality, it becomes clearer why some Indigenous peoples are reluctant to learn or speak their language.

Finally, there is no doubt that an aging mother tongue population contributes to the extinction of Indigenous languages. If the Indigenous languages are not taught to the next generation, they will disappear.

Possible Solution

Several efforts are underway to prevent Indigenous languages from extinction. With the help of technology, Indigenous languages can be revived, reclaimed, and supported (Oladimeji et al. 2020). In this paper, designing a mobile game language-learning application based on Indigenous culture with Indigenous community involvement, especially among elders, is suggested.

The Importance of Connecting with the Elders

Seeking support from the elders is crucial to ensure language instruction is consistent with the standards and the dialect of the community. The language and Indigenous peoples' lives are connected (Desmoulins et al. 2019).

Advantages of Mobile Game Apps for Language Learning

A mobile device can be an excellent tool for learning a language due to several reasons. First, the portability of mobile apps is one of the main advantages. It allows users to use their free time more productively. Second, a mobile app may be helpful to those who are uncertain about how to pronounce vowels correctly or are afraid of being mistaken. Third, a great advantage of mobile apps is that they give learners the choice of owning the learning

tool, rather than enrolling in expensive classes or using traditional study materials. Fourth, mobile applications can provide a fun and entertaining learning experience (Cassels and Farr 2019).

The popularity of video games and mobile games has grown considerably in recent years and their popularity among young people makes them a potentially useful tool in education (Oladimeji et al. 2020). Hence, game apps can be a valuable tool to revitalize Indigenous languages. Score points of players in a certain mobile application game could be a measure of learning. It can enable the users to understand the reasoning behind obtaining a low score and utilize it to have a better learning experience following repetition (Godoy 2020). Games that use a learning scenario-based approach involve the gamers in a problem-based setting to solve problems. Hence, the players will be required to make decisions about integrated questions, experiment with the options offered, interpret feedback, and adapt to new learning methods for new insight and skill development (Godoy 2020).

General Challenges

Indigenous language technology development will be faced with many challenges and problems. Here, there are two distinct types of challenges, one associated with the Indigenous languages and another one related to mobile game apps.

Challenges Regarding Indigenous Languages

There are several reasons why dealing with Indigenous languages can be challenging. Some of these challenges are listed below (Littell et al. 2018).

- The morphological complexity of Indigenous languages is typically very high.
- Often, a single word conveys the meaning of what might otherwise be a complete clause in English or French.
- It is challenging to get a digitized text or sound available for training in most Indigenous languages.
- There are various dialects within Indigenous languages. Still, there is a lack of references to whether the orthographic standards were developed for all dialects or if only one dialect is represented in the sources and articles.
- There are several orthographies used to write the Indigenous languages. Even though the orthographic union (unification) of the language leads to a general improvement, there are still significant differences between languages based on their location or age.

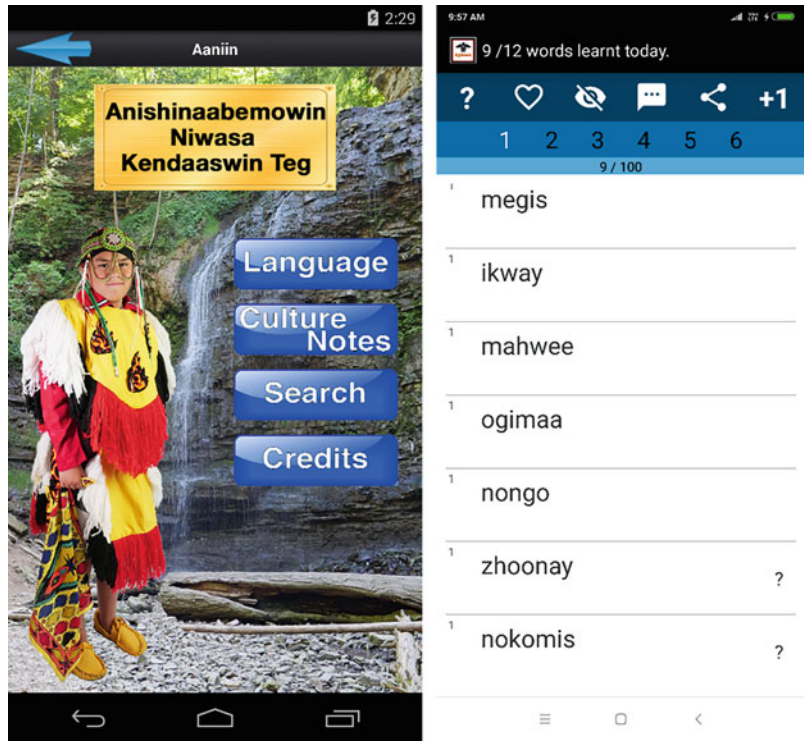
Challenges Regarding Mobile Game Apps

In addition to many other uses, mobile game apps can be useful tools for language revitalization efforts. Indigenous language learning apps can be effective when language acquisition with cultural themes is combined. Hence, it is vital to consider how it can be designed pedagogical activities and tools in a manner to respect the culture, community, worldview, protocols, and physical environments of Indigenous peoples (Cassels and Farr 2019). A technology-based community initiative must deal with the rapid pace of technological change. It is also common for apps to be updated periodically, like other software products. Those who want to use the app must have a device that is compatible with the current version. This compatibility issue may make it difficult for individuals to keep up-to-date devices since maintaining their devices may be expensive (Cassels and Farr 2019).

Games

To revitalize Indigenous languages, many efforts are being made to use traditional games or mobile games. These games are helping to keep these languages alive and provide a valuable resource for those who would like to learn and preserve these precious cultures. The following are some examples of mobile game apps for indigenous languages in Canada; see Fig. 1.

- Anishinaabemowin Niwasa (Thornton Media, Inc. 2019): This game is designed to teach players the Anishinaabe language. It features



Indigenous Language Revitalization with Stories and Games, Fig. 1 Images from mobile game app for indigenous languages in Canada: Left: Anishinaabemowin Niwasa (Thornton Media, Inc. 2019); right: Beginner Ojibwe (shotgun. experiments 2018)

a series of mini-games that help players learn vocabulary and grammar in a fun and interactive way.

- Beginner Ojibwe (shotgun.experiments 2018): This app is designed for those new to the Ojibwe language or those who are enthusiastic about learning it. The app follows a "word of the day" approach, allowing users to select up to 12 words per day to learn. It is meant to be a straightforward introduction to the language.
- Ojibway (Baxter 2017): This app teaches users the Ojibway language using professional-quality audio, pictures, and syllabics. It covers important aspects of the Ojibway culture, including history, geography, famous people, and treaties. The app also teaches common phrases, pronunciation, and syllabic writing. It provides comprehensive information about the Ojibway people, including their lifestyle, history, and notable figures.
- Cree Language (GNWT Official Languages 2016): This game teaches players the Cree language through a series of word puzzles and challenges. It also includes cultural teachings and stories to help players gain a deeper understanding of the Cree people and their traditions.

Such games provide a fun, engaging, and accessible way to learn indigenous languages in Canada, and they protect these precious languages for future generations. They are, however, typically only available for a single operating system or platform, and their static nature can lead to them being outdated.

Design Considerations

Mobile game apps can help revitalize the Indigenous peoples' languages if children and youth will be taught to speak the language using these. However, to be accepted by its audience, the mobile game application has to be entertaining and well-designed. The user interface, fast loading time, high performance, and compatibility with different mobile platforms are key factors here. If a

mobile game app did not meet these criteria, it would barely succeed.

The term cross-platform in mobile game applications refers to the fact that users of different hardware or operating systems can play the same game simultaneously. Therefore, it is very important to have a mobile game app that can run on Android, iOS, and other common operating systems and hardware.

One of the best ways to develop a cross-platform app is by using game engines. Game engines are the core software needed for a game to run properly. It is possible to have various versions of a game app for different platforms after developing a game using a game engine. Developing a cross-platform mobile game app using a game engine to teach the Ojibwe language would be an excellent idea.

Due to the need for an Ojibwe language-learning mobile app to be scenario-based, some stories from this nation can be used in the process of app design and development. Concepts such as treaty rights, tribal sovereignty, wild rice, and spearfishing are a few examples that can help mobile game apps to be better adjusted to the community's culture.

Conclusion and Discussion

In conclusion, scenario-based mobile game applications can play an important role to promote and preserve Indigenous languages and cultures by honoring the Indigenous way of life. It is also clear that interaction with the Indigenous community, in particular with the elders, and receiving feedback from them can enable an application to be suited to their needs. Hopefully, this will help to promote the awareness of the Indigenous community, especially the new generation and youth, about their language.

Information presentation methods; Serious games; Tutorials; Video games; Virtual reality

Definitions

Virtual Reality: A model of reality with which users can interact using senses such as sight, sound, or touch.

Immersive Virtual Reality: A type of virtual reality in which the user's complete view is surrounded by the synthetic environment, as if they had stepped inside the virtual world. It is usually distinguished by the high level of immersion and interactivity offered.

Information Presentation Method: The way information is conveyed to users in virtual world. It can be in various forms such as animation, video, visuals, text, audio, and pictographs.

Serious Game: A video game with a purpose beyond entertainment such as teaching users a new skill or training users to improve their existing skills on a subject.

Introduction

After early 2010s with the launch of more affordable and higher fidelity new generation headsets, virtual reality (VR) has become a very popular medium for various areas such as games, training, and rehabilitation. Despite its increasing prevalence and proven success in many topics, there are still a lot of unknowns and unexplored areas related to virtual reality. One of these areas that has not been much explored yet is information presentation methods in virtual reality. Information presentation is important in the sense that it informs users about what they need to do in the virtual world. Virtual reality offers a high degree of visualization, but it is unknown whether three dimensional instructions work better than two dimensional, for example. If not prepared appropriately, information presentation may affect user experience negatively and cause frustration in users. Thus, information presentation method is an important aspect of virtual reality. In this entry, researches conducted in this area so far are presented along with future directions and conclusions.

Dynamic and Static Information Presentation Methods in VR

Several studies that had conducted in the early years of virtual reality stated that dynamic information presentations such as animations were more beneficial in terms of cognitive aspects, than static methods such as text and pictures (Levie and Lentz 1982; Park and Hopkins 1992;

Rieber 1990). Some following studies contradicted with these prior findings, concluding that static methods might have been as effective as dynamic methods (Hegarty 2004). The reasoning behind this was that although the dynamic methods might have had advantage over static ones in terms of visualization, they also had associated pitfalls such as demanding continuous attention of the user and presenting information only for the duration of the included motion. In this sense, the static information presentation methods were available for viewing as long as the user wanted to, since they were not associated with any movement duration constraint. The required cognitive load for viewing also was lower, since they did not include any dynamic elements. A third realm of studies followed these two contradicting views, which combined static and dynamic information presentation methods and examined the effects on user experience. The researchers found out that it resulted in disjointed understanding, as some participants were not able to figure out how to integrate the two or when to focus on which one (Ainsworth et al. 2002; Anzai 1991). As a remedy, a following study suggested that having the user actively participate in the integration of picture-based and symbolic information presentations provided better user experience and increased understanding (Bodemer et al. 2004). The importance of information presentation method not only lies in the level of understanding it provides the users but also its effects on the production costs. Dynamic methods such as animation and videos are costlier and more time consuming to produce, whereas static methods such as pictures or text are usually less costly and less time consuming. Hence, it is important to understand which information method in virtual reality would provide the best user experience while being cost and time effective at the same time.

Tutorials in Serious Games

Ushaw et al. looked at the video game industry and studied which of the best practices could be adopted from commercial video games to serious games with a health focus (Ushaw et al. 2015). The best practices that were found to be suitable for adopting were: brief in-game instructions that are on-screen (not on a manual or a printed out document) and readily available to the player for the duration they like to view them; using prerecorded videos of required in-game actions and using these recordings as an in-game tutorial. Greyling and Calitz studied on developing a computerized multimedia tutorial system they named "ACCUTUT," which aimed to train prospective higher education students in using computerized admission test user interfaces effectively (Greyling and Calitz 2003). In this system, the following instruction methods were used: written, verbal, and simplistic icons (brief pictures). Researchers found out that using such assistive information presentation methods instead of requiring students to read large segments of text improved user experience and eliminated several interface problems while taking these admission tests.

Spatial Information in Information Presentation

To assist users with understanding information, some previous studies explored the use of spatial information in VR systems. Bowman et al. looked into whether using spatial information presentations inside a virtual zoo would stimulate learning and comprehension in participants or not (Bowman et al. 1999). In the virtual zoo system, the following information presentation methods were used: verbal, text, a few accompanying images (only for complex content), and audio annotations that were triggered automatically if the users were close to them. Although not evaluated in isolation, these assistive information presentation methods were observed to increase users' understanding of the layout and design on the virtual environment. The virtual zoo experience enabled students not only to learn the presented information directly but also to understand the material better as compared to traditional teaching methods. Likewise, Ragan et al. also explored effects of supplementary spatial

information on user experience (Ragan et al. 2012). Written and symbolic information presentation methods were used in the VR system and participants' performance on learning-based activities were measured. In one version, information was presented directly to the participants in the virtual environment, and in the other version, information was wrapped around the participant on surrounding displays. Experiment results showed that spatial information presentation provided improved memory scores whereas no improvements were observed for higher level cognitive activities, such as critical thinking.

Commonly Used Information Presentation Methods in VR Systems

Unless they rely solely on human tutors who will explain the users how to use the system and what tasks to perform in it, almost all VR systems include some form of instructions. In this subsection, we present a compilation of recent VR systems and the information presentation methods they utilized. These studies did not focus on exploring effects of instruction methods in VR on user experience; however, observing the common choices of instruction methods chosen to be used by the recent studies may shed light on understanding information presentation methods better.

Oliveira et al. utilized text-based instructions in their VR system for industrial equipment maintenance training (Oliveira et al. 2007). Galvan-Bobadilla et al. used several different instruction methods (animated, written, and verbal) in the VR system they developed for training users on maintenance of underground power distribution lines (Galvan-Bobadilla et al. 2013). Stinson and Bowman utilized text-based instructions in their VR system that aimed to train athletes on handling high-pressure situations (Stinson and Bowman 2014). Carlson et al. chose to include prerecorded video-based instructions in their VR training system for assembly tasks (Carlson et al. 2015). Chittaro and Buttussi included text-based instructions and very brief pictures in their VR serious game for aviation safety training (Chittaro and Buttussi 2015). Aggarwal et al. also utilized text-based instructions and very brief pictures for presenting information in their VR laparoscopic surgery training curriculum development studies (Aggarwal et al. 2009). Corato et al. chose to include real-time animation overlays along with text-based on-screen instructions as information presentation methods in their VR system for training surgery staff on hand-washing procedures (Corato et al. 2012).

Conclusion

Although some previous studies have examined effects of information-presentation methods on user experience in VR, there are still no well-established design principles recommending which method works best for different aspects such as entertainment, training, learning, memorization, or retention. More studies are needed to identify effects of information presentation methods on user experience for improved VR experiences.

Synonyms

Advertising; Augmented reality; Campaign; Virtual reality

Definitions

Augmented reality (AR) is a simulated, but enhanced, reality that combines both computer-generated virtual and real-world data to enable users to perform real-time interactions with digital graphics, imagery, and objects, in a seamless way and with an illusion of these layers of information coexisting in the same space.

Mixed reality (MR) refers to an umbrella concept from the reality-virtuality continuum to allow users to experience the key efficiencies of both AR and VR technologies. This technology analyses users' surrounding real-world environment before producing a digitally generated graphical reality.

Virtual reality (VR) is an assembly of technologies that offer immersive, interactive, and information-rich experiences when users are able to interact with objects and realities in a computerized, simulated, real-time 3D virtual environment by employing their senses and skills.

Introduction

A recent research report by the International Data Corporation (IDC) (2017) forecasts that the global revenue for both augmented reality (AR) and virtual reality (VR) will reach $13.9 billion in 2017, a dramatic increase from $6.1 billion in 2016. The compound annual growth rate of AR and VR will reach $143.3 billion in 2020 (IDC 2017). By 2020, growth in the online retailing and digital game sectors will be the top two applications of AR/VR technologies (IDC 2017). As a result, AR/VR campaigns have been accepted into major advertising awards. For example, the Creative Arts Emmys granted Fox's *Sleepy Hollow Virtual Reality Experience* (https://www.youtube.com/watch?v=peFGMwVQXL0) an interactive media award for its creative achievement (Giardina 2017).

Digital advertising plays a particularly significant role in the growing electronic and mobile commerce markets. Its sheer size has prompted advertisers to experiment with AR/VR technologies (Metz 2015a, b). Past advertising literature has observed that AR/VR technologies are able to offer the benefits of immersive storytelling, product demonstration, and emotional arousal to engage consumers in advertising and marketing campaigns, according to Interactive Advertising Bureau (IAB) (Klie 2016). Furthermore, the rapid diffusion of smartphone devices also creates a ubiquitous communication environment that allows consumers to constantly interact and engage with advertising campaigns (Persaud and Azhar 2012). The social media population now accounts for 37% of the world's population or 60% of Americans (Jorner 2017). The pervasive presence of social media further prompts advertisers to take advantage of the opportunities in integrating both platforms (Swant 2017a). For example, Facebook debuted its Facebook Spaces AR platform to offer its users AR experiences through an Oculus Rift headset (Swant 2017a).

This entry will go over the definitions of AR and VR, discuss the technological developments relevant to the advertising industry, examine major determinants in their adoption by advertising practitioners, and provide AR/VR campaign examples to demonstrate their potential.

Virtual Reality (VR)

VR is defined as a computer-generated and simulated environment in which users are immersed in a virtual environment to experience the presence of other objects or realities through interaction with them (Heim 1998; Hsu 2017; Kerrebroeck et al. 2017). VR technologies have been used in military training as early as 1995 (Kerrebroeck et al. 2017). Recent VR applications range from aviation, medical (Claudio and Maddalena 2014; Hsu 2017), advertising (Bazilian 2017a, b; Johnson 2017a, b, c, d), marketing (Heine 2017; Javornik 2016), etc.

As an emerging media platform for advertising practitioners, VR is characterized with three key attributes, or "Three I's": immersion, interactivity, and information intensity (Claudio and Maddalena 2014, pp. 2–3). First, VR users are fully immersed in a computer-mediated environment through VR headsets such as Sony PlayStation VR, HTC Vive, Oculus Rift, Google DayDream View. Scholars have found that immersive VR experiences often strongly affect adults' attitudes, behaviors, and thoughts (Bailey and Bailenson 2017). As a psychological state that is often experienced by VR users in the virtual environment, immersion is considered to be the most important aspect of VR technologies (Kerrebroeck et al. 2017).

Secondly, interactivity refers to the human-computer interactions made possible by VR gadgets such as VR helmets that offer high 3D sights and sounds, and high-resolution quality, as well as motion-tracking hardware and software to interact with the virtual world (Claudio and Maddalena 2014). As defined by Steuer (1992), this concept refers to "the extent to which users can participate in modifying form and content of a mediated environment in real time" (p. 84). Interactivity of VR campaigns thus enables consumers to experience individualized and customized advertising contents. Thirdly, VR also provides ample information and functionality that involve all human senses (such as hearing, kinematic, proprioceptory, and vision) to allow users to meet their entertainment and hedonic gratifications (Kerrebroeck et al. 2017).

A VR system is composed of several different technologies that include (1) a graphic rendering system; (2) gloves, trackers, and user interface to detect and input users' movements; (3) output devices to facilitate aural, haptic, and visual interactions in the VR environment; (4) a software to model virtual objectives and to construct databases; and (5) a system to deliver VR sensory stimuli such as visual display technology to offer users interactive and immersive experiences (Claudio and Maddalena 2014).

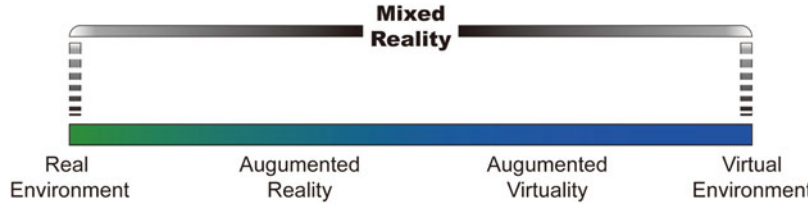
Advertising practitioners who would like to take advantage of the potential of VR technologies are still faced with several challenges. First, the potential of VR technologies in advertising lies in their diffusion and the attractiveness of related applications. According to a survey of 811 American adults by YuMe, a majority of consumers have heard about (around 47% of survey participants), but cost has been ranked as the most important determinant of VR adoption (Baumgartner 2016). Similarly, Bazilian (2017b) also concurred in another survey of 1,000 people between 18 and 64 years old that 37% of the participants decided against buying VR devices after realizing its high cost, and 64% of them agreed that they would buy VR devices if they were less expensive. Thanks to the popularity of smartphones adopted by 68% of the US adults (lessonly.com 2016), this challenge may be resolved sooner.

Secondly, other VR researchers have also observed other important determinants including heightened consumer expectations, availability of VR headsets, new ways of thinking in designing more interactive contents, etc. (Klie 2016). Thirdly, a country's telecommunications infrastructure will also affect if the immersive potential of VR technologies can be fully realized without data transmission delays. Consumers of VR technologies will continue to expect higher frame rates and image quality. As a result, data demand of VR devices are expected to exceed those of 4 K. According to Juniper Research, data consumption is predicted to grow from 2,800 PB in 2017 to over 21,000 PB in 2021 (Laposky 2017). Lastly, the future development of VR technologies also rely on how VR integrates with other popular platforms such as Facebook or WeChat, both of which are currently developing their own VR platforms (Johnson 2017d; Jorner 2017; Laposky 2017).

Augmented Reality (AR)

Similar to VR, augmented reality (AR) also allows users to interact with simulated digital graphics, imagery, and objects that combine both computer-generated virtual and real-world data to make real-time interactions possible, with the illusion of co-existing in the same space (Rese et al. 2017; Van Krevelen and Poelman 2010; Williams 2009). Researchers have claimed that AR is an important branch of VR because both integrate virtual digital information into a 3D real environment in real time (Chen et al. 2016). Therefore, the definitions of AR center on its virtuality, enhanced telepresence and flow experience, and a sense of immersion. For example, Carmigniani and Furth (2011) defined AR as "a real time direct or indirect view of a physical real-world environment that has been enhanced/augmented by adding virtual computer-generated information to it" (p. 342).

Figure 1 best captures how realities are created in the virtual world and where augmented reality stands in this popular Reality-Virtuality



Integrating Virtual Reality and Augmented Reality into Advertising Campaigns: History, Technology, and Future Trends, Fig. 1 A continuum of realities in the virtual world. (Adapted with automatic permission from Kim et al. 2016, p. 162)

(RV) continuum (Milgram et al. 1994). As seen in Fig. 1 (adapted from Kim et al. 2016, p. 162), mixed reality (MR), or Hybrid Reality, is often used as a stand-along application or can be used as an umbrella term that encompasses variations, yet captures "the core efficiencies" of both AR and VR technologies and applications (Milgram et al. 1994; Reality Technologies n.d.; Pando 2017). MR include augmented reality, augmented virtuality, and other mixed reality applications (Reality Technologies n.d.). The concept of mixed reality refers to an application by which real and virtual world objects and people are integrated with the virtual environment where digitally generated and physical objects are juxtaposed to co-exist and to allow users to interact in real time (Milgram et al. 1994; Milgram and Kishino 1994). MR is therefore different from AR because MR analyzes users' surrounding environment before projecting computer-generated contents and synthetic objects that users are able to interact with virtually (Pando 2017). In spite of the conceptual differences, we will use AR and MR interchangeably, following the current practices in the advertising and marketing industry.

As an interactive and immersive media platform, AR offers a great potential to complement what traditional advertising platforms are not able to offer through its innovative ways to interact with commercially relevant advertising contents (Javornik 2016). Unlike these media, AR is characterized with its "interactivity, virtuality (presence of elements of virtual reality), geolocation feature/location specificity, mobility (in terms of portability and wearability) and synchronization of virtual and physical/real (augmentation)" (Javornik 2016, p. 253). These characteristics have made AR a promising platform for many advertisers.

As early as 2010, HarperCollins Publishers has experimented with AR to promote Irish author, Cecelia Athern's book, *The Book of Tomorrow*, in its campaign (everydayismagical.com) (Shields 2010). With the popularity of social media platforms, the agency Stickee also employed Facebook in this multiplatform campaign (Shields 2010). Similarly, Ford's UK campaign (https://www.youtube.com/watch?v=bl8T9oYO5vY) targeted young demographics to encourage their purchase of Ka car model. The technology allows mobile phone users to view images superimposed virtually onto another pictures in a video kiosk (Clifford-Marsh 2009). Advertisers often integrated AR with other integrated marketing communications (IMC) platforms. In its 2017 AR campaign (http://www.benjerry.com/flavors/special-stash), Ben & Jerry worked the advertising agency, 360i, through Facebook's latest augmented reality platform to promote its newly launched marshmallow-flavored ice cream (Johnson 2017d; Loop 2017). This AR campaign also integrated a digital game platform to allow players to use a smartphone's rear-facing camera by allowing them to catch marshmallows falling from the sky. If consumers missed more than five marshmallows, the AR game ended (Johnson 2017d). The ice cream cones at the bottom of the campaign site tracked how many marshmallows have been missed (Johnson 2017d; Loop 2017).

Scholz and Smith (2016) proposed the "layer/world metaphor" (p. 149) to describe the applications of AR in advertising. Advertisers developed digital information layers made up of

pictures, texts, and videos that later overlay with physical objects (e.g., advertisements, landscapes, product packages, street scenes) in the real world (Scholz and Smith 2016). Through digital screens or holograms on digital out-of-home billboards, smartphones, or other video installations, uses are able to experience their virtual presence and "hybridized realities" (Scholz and Smith 2016, pp. 149–150) that generate an illusion that they interact seamlessly and in real time with the computer-generated objects.

In the following 2014 Pepsi Max Unbelievable AR campaign in London (https://www.youtube.com/watch?v=Go9rf9GmYpM), a bus stop was rigged with an digital display capable of producing AR experience to daily commuters. The 6-sheet digital screen displayed computer-generated UFOs, giant hostile robot, and escaped wild tiger images that overlay with live feed of the street (Dyakovskaya 2017). This campaign generated very positive results with 30% sale volume increase, 120,000 mentions, likes, and shares in major social media channels, and 87% earned view rate (Dyakovskaya 2017). The campaign has demonstrated how a UFO attack scenario was overlaid with the street scenes in London (Dyakovskaya 2017). The potential of AR-enabled billboard can be maximized when interactivity is embedded in the campaign when consumers are able to participate in the interactions with AR contents (Szymczyk 2009). Refer to the campaign video site (https://www.youtube.com/watch?v=Go9rf9GmYpM) to experience the role of AR in enhancing consumer engagement.

To conclude this section, *Fortune* magazine predicts that AR will generate $120 billion in revenue by 2020 (Gaudiosi 2015). Gartner (2010) also predicted that AR could be considered as one of the promising top ten technologies in the information-communication technologies (ICT) sector (cited in Kim et al. 2016). At the 2015 Consumer Electronics Show, AR has the potential to "disrupt anything with a screen" (cited in Scholz and Smith 2016, p. 150). The advent of mobile AR content is likely to create the greatest influence on AR applications in the next 5–10 years (Heine 2017; Szymczyk 2009). AR users will be able to personalize their own immersive mobile AR experiences in advertising, entertainment, gaming, retailing, sports, contexts to complete their consumer decision-making journeys (Heine 2017; Rese et al. 2017; Shapiro 2017).

Table 1 below offers a good summary of major advantages of AR and VR as two emerging interactive technologies. These media characteristics offer potentially promising applications for the advertising professionals. For example, interactivity will allow advertisers to develop fully interactive digital ads that allow users to interact and modify ad contents. The hypertextuality feature will enable consumers to access product information embedded in the digital ad and to connect to e-commerce and mobile commerce site to

Integrating Virtual Reality and Augmented Reality into Advertising Campaigns: History, Technology, and Future Trends, Table 1 Technical characteristics of AR and VR technologies

Media characteristics of interactive technologies	Definition
Interactivity	Machine and personal interactivity, feature-based or perceived, composed of control, responsiveness and two-way communication
Hypertextuality	Potentially high number of linked sources
Modality	Diversity of content representation
Connectivity	Technological capability of expanding and sustaining a model of network, where many users can be connected among themselves
Location-Specificity	Specificity with which a technology and its user can be targeted based on the precise geolocation
Mobility	Portability and wearability that allow a mobile use
Virtuality	Combination of virtual elements that causes immersion in an environment constructed with computer graphics and digital video

Reprinted from Journal of Retailing and Consumer Services, 30, Ana Javornik (2016), pp. 252–261, with permission from Elsevier

purchase advertised products. In addition, the multimodality of both AR and VR technologies has blurred the traditional boundaries of print, electronic, out-of-home media, and emerging media. As a result, traditional print ads are able to offer videos through AR, VR, or holograms, such as Porsche's holographic magazine ad (2016) (https://www.youtube.com/watch?v=XThnCB3s8y0). Connectivity has led to the creation of social media advertising and electronic word of mouth to facilitate the marketing communication processes. Both location-specificity and mobility characteristics allow advertisers to send location-sensitive mobile advertising to consumers' mobile devices and create a pervasive mobile environment. Finally, virtuality of the VR and AR platforms has generated a potential to integrate with other media platforms to create fully immersive advertising experiences.

We used the following VR and AR campaigns to demonstrate the benefits of integrating these two emerging technologies into advertising campaigns to generate positive results.

Integrating AR/VR into Advertising Campaigns

- Campaign Case #1: KFC's "The Hard Way" Virtual Training Escape Room VR Campaign (2017) (https://www.youtube.com/watch?v=GAlD0h9vCEc) (https://www.youtube.com/watch?v=JX5RmKcO_j8)
- Kentucky Fried Chicken (KFC) launched its 25-min VR video game campaign, "The Hard Way," that required users to learn how to fry chicken thighs and wings before they could escape from the virtual Colonel Sanders' secret lodge (KFC Corporation 2017; Swant 2017b). This VR campaign was developed by Wieden + Kennedy's emerging technologies branch, W + K Lodge (Swant 2017b). Though not intended for the public, the campaign was designed to train KFC's new "screen-obsessed" Generation Millennial cooks to have a better understanding of the brand's personality, according to Bob Das, KFC's head check in the USA (Jardine 2017; Swant 2017b). KFC has been proud of its products, claiming "It's made in the hard way" (KFC, https://www.kfc.com/about/how-kfc-makes-chicken). Cook trainees were challenged to interact with the computer-generated objects through an Oculus Rift headset and controller and learned the laborious five-step processes of inspecting, rinsing, breading, racking, and pressure-frying KFC's chicken products before placing these virtual objects in Colonel Sanders' mouth to complete the training (Jardine 2017; Swant 2017b). KFC has planned to use more VR e-learning and training contents to help train its cooks in its multistep and rigorous Chicken Mastery Certification program (KFC Corporation 2017). VR technologies in this campaign have allowed KFC to communicate its corporate mission statement with a fun and hand-on experience. As seen in KFC's press release (2017), "What excites us is experimenting with new tools and mediums to tell stories. VR became an obvious choice to create an immersive experience that teaches trainees how to make KFC's Original Recipe. The escape room concept builds on the pure training and utility of the experience into something that's also entertaining and connected to KFC's iconic founder." Campaign Case #2: NHS Blood and Transplant AR Campaign in UK (2016) (https://www.youtube.com/watch?v=-zNWP4lzrJQ)

This AR campaign was launched in Birmingham and London though its interactive out-of-home digital billboard to change people's stigma about blood donation (Marketing Week 2016). The campaign was created by agency, 23red that prides itself to "change behavior for the better" (Marketing Week 2016). This AR campaign was an excellent demonstration of how an AR app could make the best use of its interactive and multimodal capabilities to create "experiential activities" to increase the awareness of and actual behaviors of blood donations (Benjamin 2016).

The interactive digital billboard showing a sick patient includes a strong message, "I need your blood donation. Can you help? Show your

support by filing a virtual bag." Spectators were given a sticker that could be detected by visual recognition on their smartphone (Benjamin 2016). Afterwards, the AR app allowed them to donate virtually their blood that will ultimately fill out an empty blood bag. Refer to the campaign video link (https://www.youtube.com/watch?v=-zNWP4lzrJQ) that demonstrates the integration of mobile app with AR technologies in this campaign.

As shown in the campaign video (https://www.youtube.com/watch?v=-zNWP4lzrJQ), the pale-looking patient's complexion changed when the blood bag was filled to transfuse the blood, replicating the actual process of blood donation. The digital billboard showed "It is helping already. Just an hour of your time can save or improve three lives." At the end of the virtual blood transfusion, the real patient thanked the donors and demonstrated "the power of a blood donation" (Marketing Week 2016, p. 6). Volunteers were also present on-site to hand out pamphlets about blood donations while a blood donation truck was parked nearby. In addition to its AR platform, the NHS Blood and Transparent campaign also integrated sponsored posts on major social media and organic social activity (Benjamin 2016). The campaign generated positive results with 583 new donor sign-ups across the 5th day and 77,000 viewing of the support videos. The success of this campaign lied on its abilities to make the most of AR's technical advantages to allow users to fully interact with AR contents and subsequently generate the highest level of user-campaign/brand engagement (Scholz and Smith 2016).

Conclusion

The integration of AR and VR technologies into advertising has opened up many opportunities for advertisers and marketers (Javornik 2016). There is no available academic research on which product, service, and company are most suitable to apply AR, VR, or MR technologies in their campaigns. However, quick keyword searches on the industry trade publications (AdWeek or AdAge) found that these emerging technologies have been applied to a variety of brands, ranging from Elle Magazine (O'Shea 2016), social media giant, Twitter (Cohen 2016), Disney's film promotion (Shaul 2014), Gatorade (Schultz 2015), etc.

As demonstrated in the above AR and VR campaigns, consumers are now able to interact and engage with advertisers' messages (Giardina 2017; Martin 2017), to avoid future ad blocking (Martin 2017), to build better brand awareness (Martin 2017), to connect consumers to the product through a self-referencing effect (Baek et al. 2015), to make people better attached to a brand, and to measure campaign effectiveness (Baumgartner 2016). As claimed by many marketing researchers, enhanced consumer engagement is likely to build long-term customer relationship and brand loyalty and has become a strategic competitive advantage (Monllos 2017; Scholz and Smith 2016).

A sense of immersion in the advertising communication process has been found to create consumer engagement and better advertising effectiveness (Martin 2017). Vibrant's test campaigns used VR and 360° video to compare those using traditional 2D video and found better effects were generated in terms of interaction rates (600%), content recall (700%), brand recall (2,700%), and product intent (200%) (Martin 2017). VR ads delivered through consumers' mobile devices continue to generate more positive effects in terms of interaction rates: 85% of VR/360° video versus 2.5% of mobile devices (Martin 2017).

According to a survey of agency clients by *Media Planners and Buyers Insperience*, it was reported that 67% of media buyers and planners were interested in integrating AR and VR into their digital marketing campaigns. Twenty-nine percent of them in the survey had purchased AR or VR ads for their clients (Martin 2017). In general, VR (67%) was favored over AR (17%) in their media buy (Martin 2017). In addition to their appeal to advertisers, marketing practitioners have echoed the same insights from the academic researchers. Felix Lajeunesse, Co-Director of Felix & Paul Studios, concurred with the importance of these technologies by saying, "We

wanted to create the feeling that you are experiencing this environment in a very personal way – feeling the emotion and connection between them and the environment" (cited in Giardina 2017, p. 70).

Despite the hype, the durability of these technologies remains to be a concern since their early introduction (Williams 2009). Information-intensive technologies such as AR and VR will require fast streaming speeds to transmit data to consumers' devices (Laposky 2017). Therefore, whether AR and VR advertising campaigns can be globalized to other countries with less-developed telecommunications infrastructure remains to be an issue. Advertising and marketing research is scarce except for a few empirical or theoretical studies (Baek et al. 2015; Hopp and Gangadharbatla 2016; Javornik 2016; O'Mahony 2015) examining factors to develop more effective AR/VR campaigns. Programmatic research should be conducted to understand better consumer-, system-, message-, and product-related factors to better integrate these technologies into future advertising campaigns. Furthermore, ethical challenges also emerge with "immersive storytelling" about a brand and manipulated realities by advertisers who use AR and VR (Webb 2016).

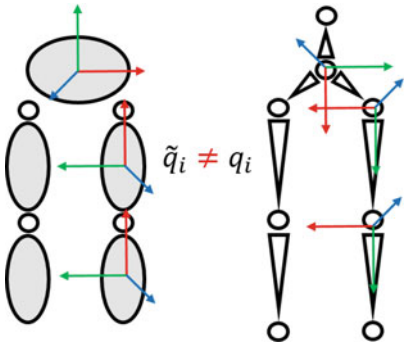
Definitions

Simulated characters offer rich and realistic interactions with users and dynamic environments. They can be thought of as compliant robots in the real world. Hence, for every unique push or perturbation, the character responds equally in a unique and realistic fashion. As the result, the immersion for the user is greatly increased and all the more powerful. This article provides insights on how to make compelling interactions with a a self-balancing bipedal character in Virtual and Augmented Reality settings. It also describes a general method to interface a simulated character with a traditional skeleton, used in modern game engines such as Unity and Unreal Engine – thereby making simulated characters more accessible.



Interacting with a Fully Simulated Self-Balancing Bipedal Character in Augmented and Virtual Reality, Fig. 1 Because kinematic skeletons (right) are designed by different digital artists, the relative rotations q_i in the parent frames are not consistent across characters and typically do not correspond to the same relative rotations $\tilde{q}_i$ in an articulated rigid body system (left). In consequence, relative rotations from a simulated character cannot be applied directly to those of a kinematic skeleton, typically used in game engines

Introduction

High-level game engines such as *Unity* and *Unreal Engine* make easily accessible state-of-the-art graphics and rendering. However, their character animation systems are based on the *state machine/blend tree* kinematic controller, which blends between motion clips. This quickly leads to repetitive animations and reactions, and increasing the realism requires exponential amounts of motion clips. In the past decades, progress has been made in the area of simulated characters, which allow to constantly generate realistic and novel motions on the fly. Because the representation of an *articulated rigid body system* (ARBS) is different from a *kinematic skeleton* (KS) used in games, it is not possible to directly use simulated characters to drive the character's motion in the game engine. Kinematic skeletons are used to deform the character's mesh through linear blend skinning (LBS). Typically it is possible to set relative rotations to the skeleton joints (but not the world transforms or access the full LBS equations). The problem is that the articulated rigid body systems and the kinematic skeletons are often different, and hold different local coordinate systems, as shown in Fig. 1. Hence it is required to transfer the joint transformations from the ARBS into relative transforms, expressed in the coordinate system of the KS. This can be formulated as an optimization problem, where a set of features are to match in the world frame, and the free variables are the joint rotations. However, this requires iterative numerical optimization, which is computationally costly. This article describes a fast analytical algorithm that solves this problem sequentially, joint-by-joint. With this algorithm, it is possible to use an external simulation and control library directly in *Unity* and have a casual user experiment with a standard bipedal controller, in particular a type of controller called SIMBICON (Simple Biped Control, Coros et al. 2010) which combines PD tracking of locomotion poses with virtual forces for balancing the center-of-mass. This article describes two different interactions with the environment usable both in AR and VR: perturbations and terrain adaptation. This allows to have an AR character walk over real world terrain or have objects thrown at the character while having him react in a unique way each time. Making these interactions compelling is actually not trivial, and this article provides insights on overcoming these hindrances.

Related Work

The standard animation system used in game engines today is the *state machine/blend tree* model which transitions between motion clips (i.e., states) similar to motion graphs (Kovar et al. 2002) and blends between *well-aligned* motion clips (i.e., blend trees), such as in *Verbs and Adverbs* (Rose et al. 1998). Putting this type of kinematic controller together requires extensive manual labor in order to loop motion clips and align them properly. Also, for every new motion and interaction, a new motion clip must be created and inserted into the graph structure, resulting in exponential growth of the graph. One way to reduce the amount of hand-crafted clips is to retarget the clips using layered inverse kinematics (IK), as to adjust the position of end-effectors to new grabbing positions, or contact points (e.g., NaturalMotion, Ikenema, FinalIK, and more).

While this approach is popular, it lacks fast response to user controls and requires a large manual effort to build and maintain. One idea to increase the responsiveness is to stich small motion clips together online using some estimate of a state-dependent cumulative reward (Arikan et al. 2005; Lee et al. 2010; Levine et al. 2012). This approach has been used in practice in the game *For Honour* (Clavet 2016), along a large data-set of human motion constructed with motion capture. Recently, Holden et al. have learned the control parameters directly with a deep neural network (Holden et al. 2017). While motion capture is still mostly available for human subjects and requires considerable time to capture and clean the motion clips, this approach is gaining traction in games to increase the realism of character motions. Unfortunately, it cannot be used directly onto a different character if the coordinate systems of the joints are different.

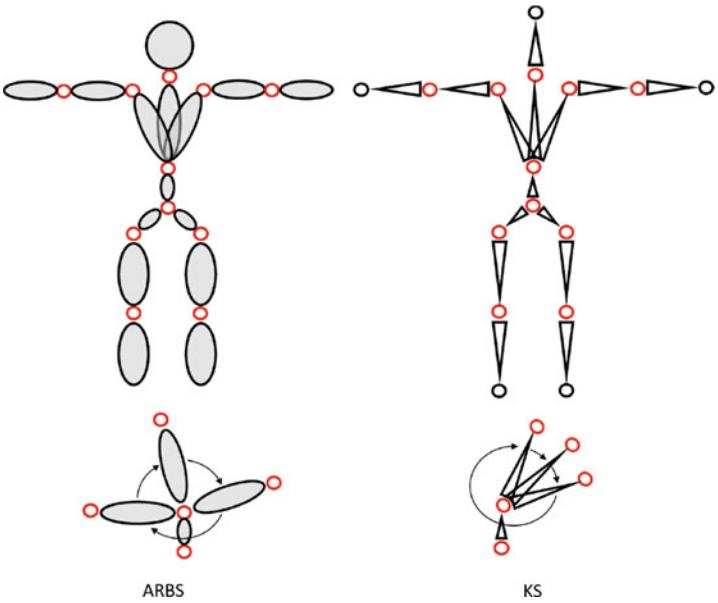
Motion transfer. Transferring motion from one character or source of motion to another character has been used and studied in many applications. This is often formulated as an optimization problem where a set of features (position, orientation) on the target character are to match the source character's features (Chai and Hodgins 2005; Choi and Ko 1999; Gleicher 1997; Seol et al. 2013).

Gleicher et al. applied this to whole motions in order to transfer motions between characters of different proportions (Gleicher 1997). Solving for individual poses (one at a time, together with smoothness) is less prone to local minima. Also many applications do not have access to whole motion, as is the case with performance animation (Chai and Hodgins 2005; Seol et al. 2013). The methods above use iterative numerical algorithms to solve the optimization problem, while in contrast, this article describes an analytical solution – assuming the same topology and access to the full source motion.

Others have used corresponding motion clips to compute an explicit transfer function from pose-to-pose (Dontcheva et al. 2003; Yamane et al. 2010; Rhodin et al. 2014), typically through a regression (Dontcheva et al. 2003) or through a shared sub-space (Yamane et al. 2010). However, an explicit transfer function is never completely accurate and leads to drift in visually important features such as foot contacts, hence requiring additional optimization iterations to fix.

Simulated characters. Another vision to increase the realism of characters is to embed them in a simulation, as if in the real world. This is a long and lasting effort in computer animation, as seminal works started with manually crafted controllers for human athletics in 1995 (Hodgins et al. 1995). Since then, controllers have been specifically engineered for locomotion using simplified balance models such as the inverted pendulum (Yin et al. 2007; Coros et al. 2010; Lee et al. 2010; Coros et al. 2011). While these controllers are very robust, they can only track locomotion and do not extend easily to other types of motions.

Many have tried to use inverse dynamics to track motion capture, assuming knowledge of the full equations of motion. Given the dynamics of the system in generalized coordinates, it is possible to estimate the torques required to match acceleration-based targets (e.g., mocap



Interacting with a Fully Simulated Self-Balancing Bipedal Character in Augmented and Virtual Reality, Fig. 2 Using the naive joint-to-joint structure leads to more freedom of motion for the simulated ARBS compared to the KS. In consequence, some poses in the simulation cannot be reached by the kinematic skeleton in the game, as shown by the example with the upper body at the bottom of this figure

targets) by solving a quadratic program constrained to match dynamics and ground reaction forces (Abe et al. 2007; Da Silva et al. 2008; Macchietto et al. 2009; Mordatch et al. 2010; de Lasa et al. 2010; Levine et al. 2012; Rabbani et al. 2014). In practice, this controller requires parameter fine-tuning and feasible objectives. Recently, there has been a renewed interest in using reinforcement learning to learn robust feedback policies for a great class of motions (Tan et al. 2014; Peng et al. 2016; Peng et al. 2017) or guided learning by alternating between open-loop control optimization and feedback fitting through regression (Liu et al. 2016).

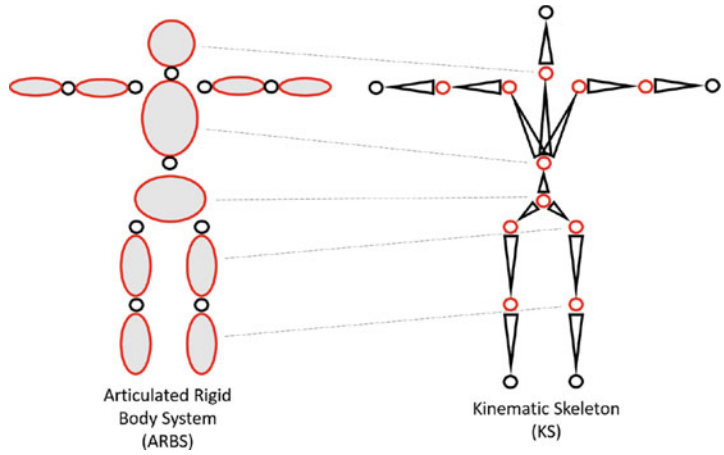
While physics-based controllers are an exciting approach to character animation, they remain out of reach to casual users and interaction designers that operate in high-level game engines. By providing a familiar interface – the kinematic skeleton – around these controllers, the possibility to use them in many applications is greatly increased.

Fast Pose Transfer

This section describes how to transfer the motion from an *articulated rigid system* (ARBS) to a *kinematic skeleton* (KS) typically used in game engines and motion authoring software such as Maya. It is first required to define which type of ARBS our transfer algorithm supports. The naive approach to building an ARBS from a KS is to associate joints together. However, this leads to an excess *freedom* problem. In other words, the ARBS can reach configurations the KS cannot, thus preventing from directly transferring the transforms from the former to the later, as shown in Fig. 2. The solution to this problem is to associate the KS joints to a rigid body, as shown below in Fig. 3.

With a suitable ARBS, it is possible to tackle the problem of transferring the motion from the ARBS to the KS. Since animation systems in game engines typically allow to only set relative rotations to the joints, it is required to recover relative transforms. Note this cannot be simply computed directly from one and applied to the other, as the parent coordinate systems differ in each model, as shown in Fig. 1. The main insight behind this solution is to compute the absolute world transform, relative to the initial transform and transfer this quantity to the KS, and then recover the local relative joint transforms.

More formally, the root position for the ARBS is denoted as $\widetilde{u}$, the local rotation as $\widetilde{q}$, and the



Interacting with a Fully Simulated Self-Balancing Bipedal Character in Augmented and Virtual Reality, Fig. 3 Our solution to avoiding excess freedom of the ARBS: the joints on the kinematic skeleton (KS) correspond to rigid bodies on the ARBS – the ARBS should be the dual of the KS

world rotation as $\widetilde{Q}$. Similarly for the KS, the root position is denoted as u, the local and world rotation as q and Q, respectively. Time is denoted $*(t)$ and the index i is a notation abuse to traverse the joints in a hierarchy with $i-1$ being the parent of i.

At the beginning, the initial root offset between the ARBS and KS is stored, as well as all the world orientations of the ARBS bodies and KS joints:

$$\text{Root off set}: \quad \Delta x(0) = \widetilde{u}(0) - u(0) \tag{1}$$

$$\text{World orientations}: \quad Q_i(0), \widetilde{Q}_i(0) \tag{2}$$

Then the process starts from the root joint of the KS, and sequentially traverses down each chain of joints/bodies to transfer the rotations from the ARBS bodies in world, to relative joint rotations in the KS, as follows:

First, we compute the ARBS rotation relative to its initial pose in world frame:

$$\widehat{Q}_i(t) = \widetilde{Q}_i^{-1}(0)\widetilde{Q}_i(t)$$

Then we compose the ARBS rotation with the initial KS world rotation to obtain the current KS world transform:

$$Q_i(t) = \widehat{Q}_i(t)Q_i(0)$$

Finally, we recover the KS transform relative to the parent:

$$q_i(t) = Q_{i-1}^{-1}(t)Q_i(t)$$

where Q_{i-1} represents the orientation of the parent joint. Note the root is a special case:

$$Q_0(t) = \widehat{Q}_0(t) \tag{3}$$

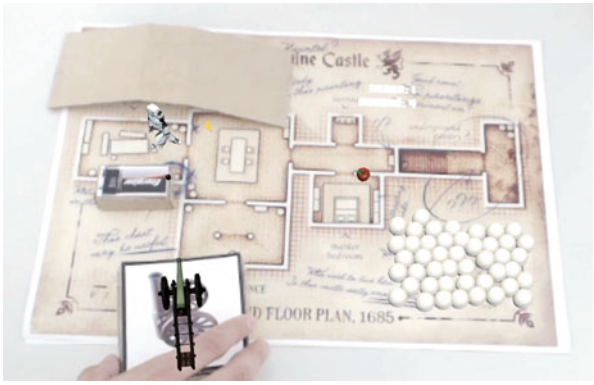
$$u(t) = \widetilde{u}(t) - \Delta x(0) \tag{4}$$

This transfer is applied at each frame of the animation. The next section describes experiments with transferring the motion from a SIMBICON-type of simulated character in VR.

AR VR Interactions

Typically simulation and control engines are implemented in fast native code (C++). However, high-level game engines use high-level managed or scripting languages such as C# or Lua. The experiments described in this section were done with the *Unity* game engine, which offers the possibility to load native libraries as plugins.

Objects in the game engine that need to interact with the character require rigid body properties

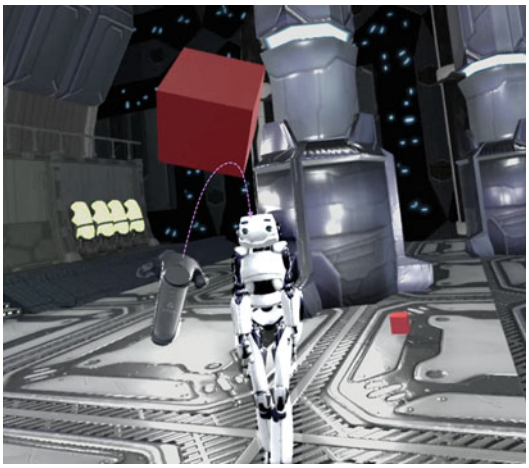


Interacting with a Fully Simulated Self-Balancing Bipedal Character in Augmented and Virtual Reality, Fig. 4 We can augment a real world environment with the virtual simulated character. The simulated character can interact with real and virtual objects in the scene. Here we see virtual cannon balls shot at the character

and colliders to be given to the simulated. This works as follows: the user can tag an object as a simulated object, whose geometry is used to initialize the mass, moment of inertia, and collider shape. Given a character mesh and a kinematic skeleton, an ARBS is created and then fixed. Applications can still use different character meshes with the same bone topology, ideally with the same proportions, but note that proportions have no effect on the simulation. For example, if the legs are longer, the feet would simply penetrate the ground visually, but not affect the behavior of the simulator (Fig. 4).

Designers conducted two types of interactions with a SIMBICON character in AR and VR. The simulated character reacts to perturbations in the environment. However, the controller is designed around a simplified rigid body system with simple collision primitives (cubes and ellipses), resulting in repetitive collisions and reactions. Described next is a solution to generate more variations and increase the immersion.

Secondly, the controller seeks to maintain balance at every step. One benefit of this is the ability to cope with various terrains. It is possible to detect objects in the environment and have the character walk over different terrain profiles. Also, the designers created a new type of game where the user tries to steer the character towards a goal, by manipulating the ground underneath the character. But first, before delving into the meat of things, the SIMBICON controller is briefly described.



Brief SIMBICON Description

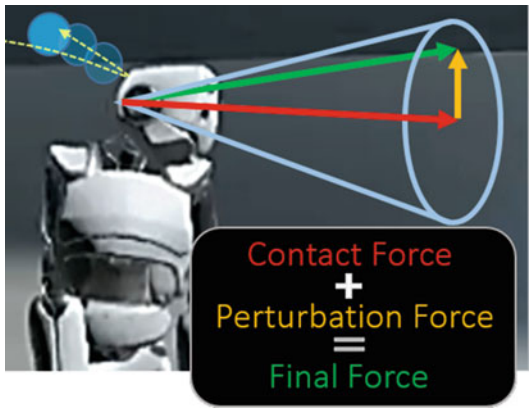
This controller relies on a simplified analytic balance model to perform locomotion. A few interpolated keyframes define the target poses for a walk cycle. To maintain balance, the foot placement position is computed with an inverted pendulum model, and the corresponding leg shape in the target pose is determined through an analytical inverse kinematics (IK). The torques driving the simulation are computed through PD-control (given the target pose), together with virtual forces – using the Jacobian transpose – to better control the velocity and root orientation of the character.

Perturbations

Users experimented with throwing objects at the simulated character in both AR and VR. While

Interacting with a Fully Simulated Self-Balancing Bipedal Character in Augmented and Virtual Reality, Fig. 5 Character can walk over real world terrain, as show on the left here with cardboard in the shape of a bridge. On the right, we see a balancing game in VR where the user controls a ground with two vive controllers

seeing the character's ability to self-balance is fun, the reactions to the perturbations became *visually* repetitive even though they are being generated online through the simulator. It could be due to the simple collision primitives used to model the character's mechanics. To have more variations in the reactions, without increasing the complexity of the model, it is possible to detect the collisions with objects, recover the contact force, and slightly deviate its direction within a cone radius.



Note that several alternatives were tried, such as adding multiple collision detection primitives to have more diversity in the contact configurations, as well as simply adding random forces at contact events. In the first case, more primitives did not improve much the drama and caused the simulator to slow down. The second idea was hard to fine tune properly and led to this solution: generate a cone based on the collision point and direction, as well as magnitude, and sample a random vector inside this cone, which would then be applied as the new force. This resulted in more variate behaviors.

Balancing the Character

A self-balancing mechanism can be quite an amusing feature to watch and interact with. A small game was devised where the user controls the plane below the character. The character moves towards the steepest point on the plane. This allows the user to guide the character towards objectives (milestones) by tilting the plane. The player has to carefully tilt the plane such that the inclination does not exceed the characters capabilities, which would make the character fall. Figure 5 shows a screenshot of the balance game.

Conclusion

This entry described a solution to using advanced simulated characters in high-level game engines such as Unity. This allows casual users to create interactive AR and VR games centered around realistic reactions to perturbations and self-balancing, which would be laborious to setup with the mainstream *blend tree* type of controller currently offered in game engines.

Definition

Augmented reality is a technology that combines virtual and real worlds in real time to help users complete their work or to provide users new experiences.

Introduction

Augmented reality technologies have been widely applied to military, industry, medical, and entertainment areas. The rapid spread of smart mobile devices such as smart phones and smart pads has made it possible to experience AR on smart mobile devices. Various AR applications including games have been developed on mobile devices using sensors such as a camera, a GPS, and an inertial sensor, yet most of them only provide simple interaction for the users. Better 3D interaction techniques are needed to extend the usability of mobile AR applications.

In this article, we will introduce a 3D interaction technique suitable for mobile AR applications developed at the mixed reality and interaction (MRI) laboratory recently. The 3D interaction technique had been developed concentrating on object manipulations.

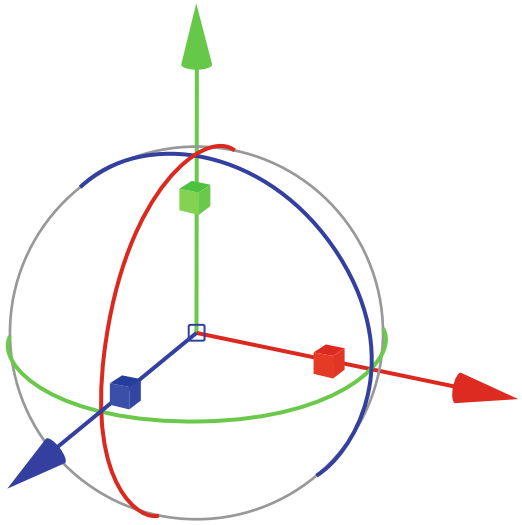
State-of-the-Art Work

3D Interaction in AR Environments

There is little research on interactions of mobile AR systems with a small display. Anders Henrysson et al. developed two interaction techniques. They used an AR-enabled mobile phone as a tangible interaction device. In Henrysson et al. (2005), the mobile phone itself was manipulated to control an object after selecting it in a 3D AR environment. In Henrysson and Billinghurst (2007), they extended the interaction technique developed in 2005 for mesh editing. They selected multiple points on a mesh and the selected vertices are locked relative to the camera. Now a user could move the mobile phone to translate and rotate the selected object or points after they chose the motion type.

Touch-Based Interaction for 3D Manipulation

Touch-based interaction techniques have been applied to manipulate 3D objections in a few virtual reality systems. These interaction techniques are categorized into two types: constrained and unconstrained. Constrained interaction techniques are able to manipulate 3D objects precisely. The constrained interaction techniques separate the control of degree of freedom (DOF) to restrict the movements of 3D objects. A widget, which acts as a visual guidance for the predefined constraints, is typically used to restrict the movements of 3D objects in the constrained interaction techniques. Figure 1 shows a standard 3D transformation widget. A user can select one of three arrows in the widget to set a translation direction or one of three circles to set a rotation axis. Any



Interaction with Mobile Augmented Reality Environments, Fig. 1 A standard 3D transformation widget (Cohé et al. 2011)

user's motions are then applied along the selected direction or the selected rotation axis.

A boxlike widget, tBox, was developed in Cohé et al. (2011). The edges and the faces of tBox were used for translation and rotation of the selected object, respectively. Users can select and manipulate edges and faces of tBox easily with a fingertip. Widgets were designed to be more tolerable to imprecise touch inputs even though careful touch positioning was still necessary. Schmidt et al. developed a single touch interaction technique with transient 3D widgets (Schmidt et al. 2008). Stroke-based gestures were used to create translation and rotation widgets. The standard click-and-drag interaction was used for manipulation.

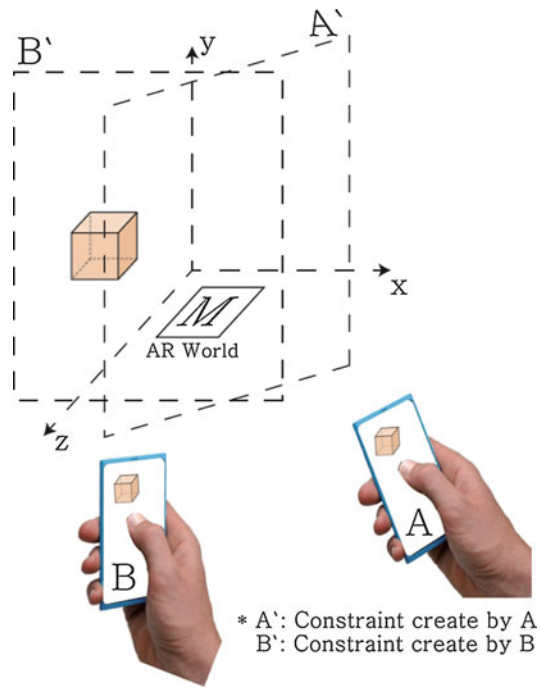
A few constrained interaction techniques have been developed for multi-touch inputs without a widget. Oscar K.C. Au et al. introduced the widgetless constrained multi-touch interaction on a 10.1 inch display (Au et al. 2012). A user selected the constraint without directly touching the constraint mark. The orientation of two touched fingers was compared with the predefined axes to select the constraint. The constraint marks were displayed only as a visual guidance to users. This solved the fat-finger problem causing an error on a device where the screen elements were too small compared to a finger.

Unconstrained interaction techniques do not use a 3D transformation widget that visually guides possible motions of a 3D object. Users can transform an object along an arbitrary direction or axis with the unconstrained interaction techniques. Users can also translate and rotate a 3D object simultaneously with the unconstrained ones so they are typically useful for fast and coarse manipulations.

M. Hancock et al. introduced the Sticky Tools technique in Hancock et al. (2009) to control the full 6DOF of objects. Users select a virtual object by touching it with their two fingers. Users move the two touched fingers and rotate the two touched fingers relative to one another to manipulate the virtual object. While users manipulate the virtual objects, user's two fingers should stay in touch with it. Anthony Martinet et al. developed DS3 (Depth-Separated Screen-Space) interaction techniques to manipulate 3D objects in a multi-touch device (Martinet et al. 2012). They combined constrained and unconstrained approaches and applied different techniques for translation and rotation. The selected object was translated along the axis or the plane defined with one or two fingers. It was rotated freely using the constrain solver, which was introduced by Reisman et al. in Reisman et al. (2009). Translation and rotation were clearly separated by the number of fingers directly in contact with the object. Nicholas Katzakis et al. used a mobile device as the game controller in Katzakis et al. (2011). They developed an interaction technique that could control a 3D cursor on a large display without directly touching the large display. The plane defined by the orientation of a mobile device was casted on the large display. The user could move the cursor on the casted plane using touch inputs on the display of the mobile device.

The last three interaction techniques are good solutions for a virtual environment with a touch-based display, but they cannot be directly applied to mobile AR environments with a small display. The Sticky Tools and DS3 interaction techniques require direct contacts with an object. This requirement is not applicable for a mobile AR

system. Fingers will occupy too much area of the display. The constraint solver could be burdensome for the processor of the mobile device, which has limited processing power. The interaction technique proposed by Oscar K.C. Au et al. could be applied to the device with a small display because they do not require direct contact with the constraint marks. The possible problems with this technique are clutter caused by visual guidance and two required touched fingers. The plane casting interaction developed by Nicholas Katzakis could be adapted to a mobile AR environment since the position and orientation of the mobile device are tracked in real time. This tracked information could be used to constrain the motion of a 3D object in the mobile AR environment. We adapted this plane casting interaction to the proposed interaction techniques.



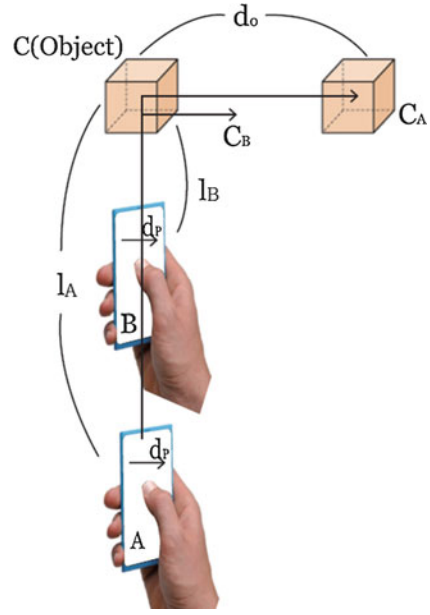
Interaction with Mobile Augmented Reality Environments, Fig. 2 Dynamic constraints

Overview

We developed a new interaction technique for mobile AR systems with following three characteristics: (1) combining constrained and unconstrained interaction techniques, (2) using relations between real objects and a smart mobile device, and (3) combining a way to manipulate real objects and a touch interface of a smart mobile device. The proposed interaction technique aims at providing intuitive and effective interaction when a user manipulates virtual objects in mobile AR world.

3D Interaction in Mobile AR Environments

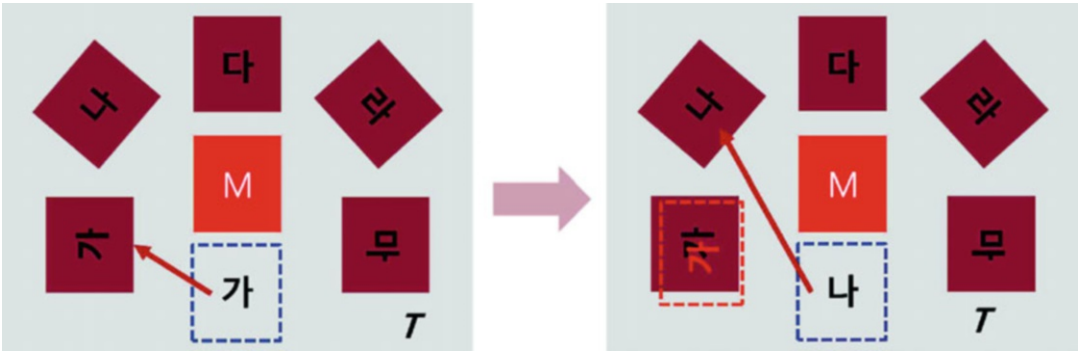
We designed a new interaction technique for mobile AR systems with three characteristics described in the earlier paragraphs. The interaction technique uses the movements of a mobile device to change constraints and a mapping ratio dynamically as shown in Figs. 2 and 3. After moving the mobile device, the plane created by the orientation of the mobile device is projected onto the coordinate of the selected virtual object in an AR world. For example, the mobile devices



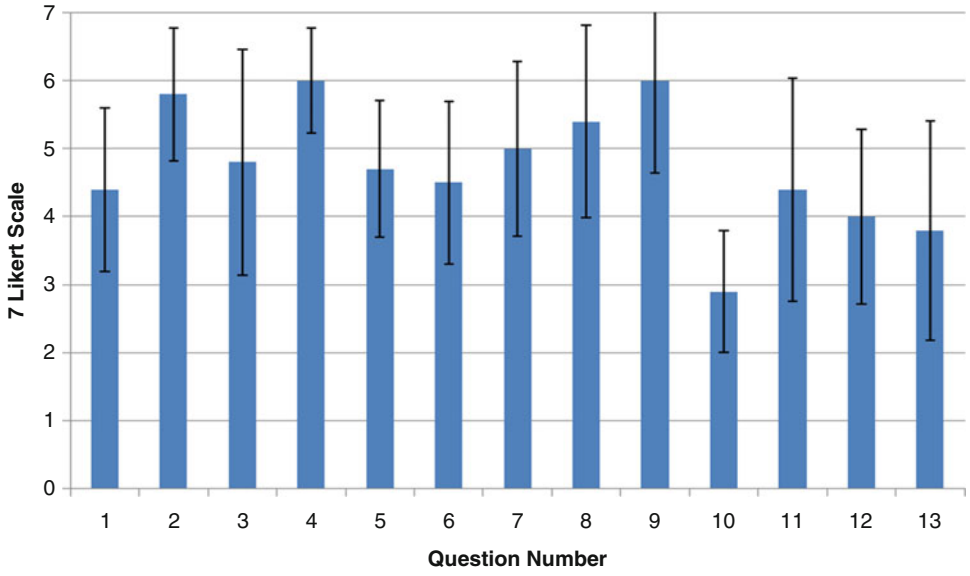
Interaction with Mobile Augmented Reality Environments, Fig. 3 Dynamic mapping distance

A and B in Fig. 2 are projected onto the coordinates of a cube object as plane A' and plane B' passing through the origin of the selected object coordinate, respectively. A user can translate the object along the projected plane, which is the constraint plane, by a simple drag motion shown in Fig. 4. By changing the constraint plane, a user can translate the object to any location with simple drag motions on the display. Figure 5 shows the mapping between the translations on the AR world and motions on the display. The 2D motion E on the display is projected onto the constraint plane D as E'. A user can move the selected object B along the E' direction using the 2D motion E on the display.

The moving distance of the object is dependent on the distance of the mobile device as shown in Fig. 3. When the mobile device is located at location A, the drag motion translates the virtual object C to the location C_A. The same drag motion on the display of the mobile device at B will translate the C to the location C_B. The distance between C and C_A is twice as long as the distance between C and C_B since the distance between C and A is twice as long as the distance between C and B. This mapping is represented in Eq. 1 where α is the



Interaction with Mobile Augmented Reality Environments, Fig. 4 The setting of the usability test



Interaction with Mobile Augmented Reality Environments, Fig. 5 User preference

mapping ratio between d_p, the distance of the drag motion, and d_o, the translated distance of the virtual object C.

$$d_o = d_p \times l \times \alpha \quad (1)$$

The tapping on a mode-changing button is used to change the interaction mode between translation and rotation. In the rotation mode, the axis of the rotation is defined as the axis orthogonal to the direction of the drag motion on the constraint plane created by the orientation of a mobile device. The axis b is orthogonal to the drag motion a. The scaling is done with pinch and spreading motions. The scaling is also constrained by the projection plane defined by the orientation of a mobile device. The ratio of the scaling is determined dynamically based on the distance between the mobile device and the selected object similar to the translation.

Experiments

We designed and performed a user study to evaluate the presented interaction technique. We examined the subjective intuitiveness such as ease of use, ease to learn, naturalness, preference, and fun.

We developed a docking task, manipulated virtual objects (indicated by the dotted lines), and arranged them along the real objects (indicated by the filled rectangular) on table T (Fig. 4). We asked participants to put five virtual characters on the top of the same real characters as shown in Fig. 4. Five virtual characters randomly appeared at the starting location, the lower center of T. To enforce 3D manipulation, the position, the orientation, and the size of each virtual character were randomly assigned. If each virtual object was closely posed with a similar size to the corresponding real object, it was considered as successfully docked and the virtual object disappeared, and the next virtual one appeared at the starting location again (see the right part of Fig. 4). The rectangular with the character M was the location of a pattern used for tracking the camera of a smart phone.

The usability test consisted of two periods: training and final test periods. Participants were trained until their performance improvements were saturated or they felt comfortable with the test. Participants generally took 30–45 min for the training period. The number of trials and the learning time were measured during the training period. The numbers of translation, rotation, and scaling operations and the task completion time were measured for each trial. Before the usability test, we asked participants to fill up the questionnaires to understand participants' backgrounds. The numbers of translation, rotation, and scaling operations and the task completion time were also measured during the final test. After the training and the final test period, participants were asked to fill up the questionnaires shown in Table 1 to measure the preference of interaction techniques and the opinions about interaction techniques.

Ten participants (four males and six females) with normal or corrected vision took part in the experiment. They were volunteers coming for the experiment and we gave them a small gift. All participants owned smart phones and seven

Interaction with Mobile Augmented Reality Environments, Table 1 Questionnaires to measure the participants' preferences of the interaction techniques (7 Likert scale)

No.	Questions
Q1	The interaction technique was easy to use
Q2	The interaction technique was easy to learn
Q3	The interaction technique was natural to use
Q4	The interaction technique was easy to remember
Q5	It was easy to view the pattern required for using the augmented reality system
Q6	The augmented object was lost few times, but they did not cause a big problem to complete the given task
Q7	The interaction technique was generally satisfactory
Q8	The interaction technique was fun
Q9	It was easy to move the augmented object to the target location
Q10	It was easy to rotate the augmented object to the target orientation
Q11	There wasn't a major problem to complete the given task
Q12	The size of the display was suitable for the interaction technique
Q13	It was easy to use one hand for the interaction technique

participants have heard about AR. Three participants have used AR apps before, but they only used them few times. We selected young participants for the experiment since they were generally more familiar with new technologies and more willing to learn new technologies.

Average ratings are summarized in Fig. 5. Overall, the presented interaction technique achieved good ratings in all questions except Q10 and Q13. The interaction technique was considered easy to learn, easy to remember, and fun. Users had difficulty applying rotation motion to the selected object and using the mobile device with one hand.

Conclusion and Discussion

Understanding the characteristics of mobile AR systems can lead to the development of more effective 3D interaction schemes in the mobile AR applications. Important findings from the usability study with the presented interaction technique can be summarized as:

1. The hybrid touch-based interface, combining constrained and unconstrained interaction techniques, is easy to learn and easy to remember for the given task. The participants' familiarities to the touch-based interface could affect the results.
2. Users have to view the given pattern through their cameras for AR applications using computer vision techniques. Participants were not bothered much by this requirement for the presented interface. This is an encouraging result because computer vision techniques are used often to create mobile AR applications. Participants also responded positively to the losses of augmented objects due to tracking failures.
3. Users do not want to move around the AR environment yet. The geometrical relations between augmented virtual objects and real objects are important in an AR environment, so users have to move around the AR environment. In the experiment, participants preferred to rotate the real environment, which is the board that contains all real objects used in the experiment. We would fix all real objects for the next user experiment to understand the behaviors of the participants better in an AR environment.

In addition, our experience suggests that we have to modify the rotation interaction of the presented interaction technique to provide users with better user interactions. Participants had the most difficult time when they had to rotate the augmented objects in the desired direction. Participants also provided useful comments. During the training period, they complained about discomfort in their arms caused by holding the smart phone for a long period of time. This aspect regarding discomfort should also be considered while developing mobile AR applications if they are to be truly user-friendly.

Definition

Handheld augmented reality (AR) has been widely used with smart and portable device in the applications such as education, games, visual experience, and information visualization. However, most of the handheld applications do not fully support natural interaction, and the existing 3D pop-up book has used touch-based to interact with 3D content. Therefore, this entry describes a fundamental to design an interactive AR pop-up book with natural gesture interaction using real hand. Subsequently, the real hand gesture tracking in handheld AR is explored to examine how it can track user's hands in real time. Thus, this entry describes about gesture interaction to allow the user to directly interact with the virtual objects. The user feels more realistic to interact with 3D objects using their bare hands on 3D pop-up book.

Introduction

Augmented reality (AR)33 is a technology that allows computer-generated information or digital information including text, video, 2D virtual images, and 3D virtual objects to be overlaid onto the real-world environment in real time (Ismail and Sunar 2013). The main reason people intend to develop AR application is to merge the real world into the virtual world to provide the users with information-enhanced environment (Billinghurst et al. 2008). The connection between these two worlds seems impossible back then, but now it becomes an attraction, and its potential was very overwhelming. Usually, the virtual elements are generated by the computer and made to be overlaid onto the real world, to enhance the user's sensory perception of the augmented world they are seeing or interacting with.

Nowadays, the concept of AR technology is used widely in entertainment, military training, engineering design, robotics, manufacturing, and other industries. AR technologies bring a lot of advantages to perform a task especially once it involves with design and planning. AR has the ability to perform 3D object manipulation and can provide natural user interaction techniques (Ismail and Sunar 2013). All developers take an advantage on AR technologies and believe it could help them to perform real task in virtual way easily besides reducing cost for real task and able to solve many issues which cannot be remedied in the real world.

The level of immersion for both elements of virtual and real objects in AR application refers to the merging of real and virtual worlds to produce AR environments and visualizations where real and digital objects coexist and interact in real time (Azuma et al. 2001). According to Ismail and Sunar 2013, a tracking process is very important in developing AR application and in running it in real time. The main requirements for trackers are high accuracy and little latency at a reasonable cost. The tracking of objects in the scene amounts to calculating the pose between the camera and the objects. Virtual objects can then be projected into the scene using the pose.

Augmented Reality Handheld Interface

There are three main fundamentals that can be found: tracking, display technology, and interaction (Billinghurst et al. 2008). Tracking is one of the fundamental parts in enabling technologies in AR, and it still have many problems that are unsolved (Ismail and Sunar 2013). Interaction technique issues in mobile AR and multimodal AR are becoming more popular. In vision-based interaction, hand and fingertip tracking and hand gesture recognition method are widely used to provide an easy way to interact with virtual object in AR (Chun and Lee 2012). A real-time vision-based approach was introduced to manipulate the overlaid virtual objects dynamically in a marker-less AR system using bare hand with a single camera (Cohen et al. 1989). It is natural that the collision between the human hand and the augmented object can occur during manipulation of the virtual 3D object. In AR, however, the collision happened between a virtual object and a real object; thus, the collision detection approach may be different compared with the ways in the real world. Most AR-handheld applications are not applying a natural interaction, and the user interactions mostly are using touch-based (Kim and Lee 2016). Therefore, this entry describes the interaction in an interactive pop-up book with natural gesture interaction using real hand in handheld interface.

The existing AR book which is generally known as the magic book contains 3D virtual and animated content registered on real book pages, mimicking a traditional "pop-up book" (Markouzis and Fessakis 2015). AR pop-up book is a book that involves the process of overlaying a virtual content onto the pages of a physical pop-up book. The current existing AR book that uses similar metaphor is MagicBook (Billinghurst et al. 2001). MagicBook offers the user the ability to experience the full reality-virtuality continuum. This is because the MagicBook itself is capable of changing the mode between AR and VR. Through AR display, the user is able to see a scene alike, and they could change the view mode to an immersive virtual environment. Another application that adopted the AR book metaphor is AR coloring book (Clark et al. 2011). The AR coloring book aims at augmenting an educational coloring book with user-generated AR virtual content.

Handheld interfaces have four interaction techniques that have been recently explored: touch-based interaction (Kim and Lee 2016), midair gesture-based interaction (Vuibert et al. 2015), device-based interaction (Samini and Palmerius 2016), and direct interaction (Hilliges et al. 2018). The traditional touch-based interaction methods for handheld AR cannot provide intuitive 3D interaction due to a lack of natural gesture input with real-time depth information (as agreed by Bai et al. 2013). Therefore, this entry aims to illustrate the design of natural interaction techniques in 3D spaces by handheld AR devices. Positions and movements of the user's fingertips are corresponding to the manipulations of the virtual objects in the AR scene (as recommended in Bai et al. 2013).

Augmented Reality Pop-Up Book

There are three phases carried out to develop AR pop-up book that are described in the following subsections.

Phase 1: Defining Interactivity and Storytelling for AR Pop-Up Book

The interactivity for an interactive book happens when it contains story and activities which required the user to perform and interact. The real pop-up book does offer a lot of advantages,

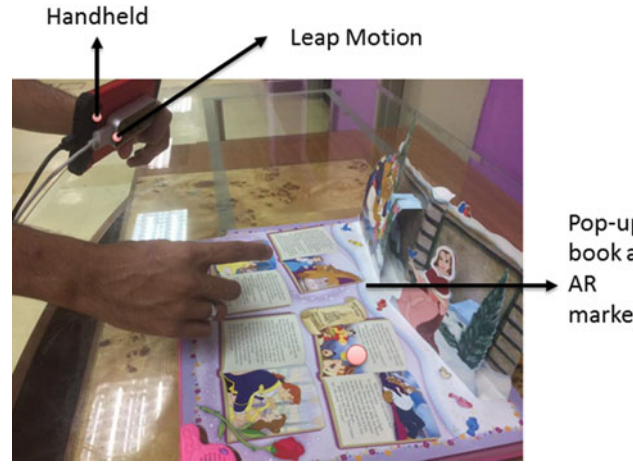
but in the transformation to more digital and interactive experience, the book offers a lot more than just a pile of heavy paper. Digital books recently have been widely restructured and recycled, yet it enhances the reading experience and more interactive than the conventional printed books. The main advantages of a digital book are that it can be customized to meet the reader's prospect (Markouzis and Fessakis 2015). This phase is conducted to design and construct the 3D contents for AR pop-up book. The 3D object built with animation is developed during this phase since the physical pop-up book does not in a digital mode. It was a fully printed copy.

An interactive storytelling enables user to take part and affects the plot of the story, creating a new genre of narrations that is much more engaging and adaptive. Several levels of interactive storytelling start from a simple branching plot to fully dynamic narration models. Interactive storytelling constitutes a new genre of literature which promises considerable learning effectiveness. This stage also defined that the appropriate 3D animation could be applied on the virtual object so the visual is more appealing and interesting. However, the storytelling has been chosen based on the current available conventional pop-up book which is entitled *Beauty and the Beast*. The physical fairytale pop-up book is being used to provide pop-up book with the storytelling. Therefore, we were transforming the existing format for real pop-up book into AR transitional and tangible in order to measure the AR experience.

Phase 2: Setting Up AR-Handheld User Interface

The phase is carried out that includes determining the display technique, tracking technique, and interaction method. This stage focuses on setting up the handheld AR interface as shown in Fig. 1. The user interface for AR application that uses the "pop-up book" metaphor has been designed. In order to create a good AR presentation, ensuring the virtual environment was displayed in a correct alignment to merge with real environment. This stage is the crucial part. Next, the display technique that was chosen is a handheld display device. The tracking technique that has been applied in this project is a feature-based. Feature-based tracking technique involves the registration of the virtual element on top of the real marker. Sensor-based was used in this project since it required the depth data to recognize the user's real hand gesture features. These elements have been prepared and examined to proceed with the next stage, the development of the AR pop-up book.

As illustrated in the diagram, it can be seen the hardware configuration. In order to overlay the virtual element on the top of real environment, the data of 3D object are loaded binding with 2D textures. In order to display the AR interface,



Interactive Augmented Reality Pop-Up Book with Natural Gesture Interaction for Handheld, Fig. 1 Setting up of the AR-handheld interface

Interactive Augmented Reality Pop-Up Book with Natural Gesture Interaction for Handheld, Fig. 2 Natural feature tracking process. (**a**) RGB image. (**b**) Gray-scale image. (**c**) Feature points

handheld device is chosen as AR display technology. The standard vision-based tracking system works to recognize the input, marker, and user hand. It recognizes the registered marker before it was loaded with the appropriate 3D object onto the scene. The user's hand required to be captured by the leap motion device (Guna et al. 2014). User interacts with the AR environment by using their bare hand as an interaction tool. The application is able to recognize user's one hand to interact with the virtual object, and the other hand holds the handheld device. Users can interact with the virtual animation by performing a define gesture that is recognized by the system.

Phase 3: Pop-Up Book Feature Tracking

This phase is conducted to design and construct the 3D contents for AR pop-up book. The 3D object built with animation is developed during this phase since the physical pop-up book does not in a digital mode. It was a fully printed copy. The phase is carried out that includes determining the display technique, tracking technique, and interaction method.

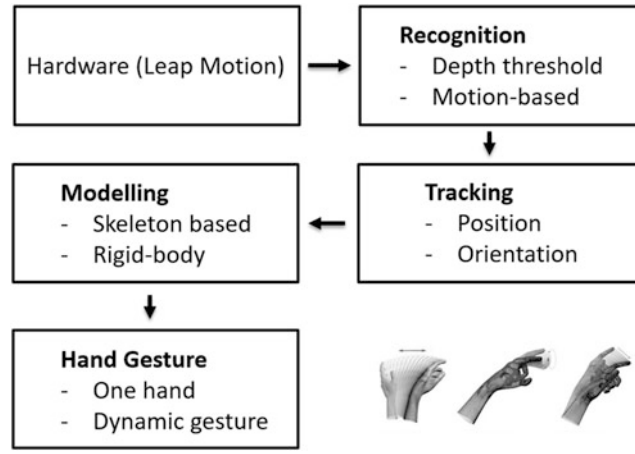
The main challenge in AR pop-up book application is to ensure the registrations and hand tracking problem are effectively solved. AR pop-up book utilizes the benefit of hand gesture recognition technique as an interaction tool in the AR environment. The tracking library is used to track the page of the pop-up book that utilizes a feature-based tracking technique.

Figure 2 shows the natural feature tracking process. The original RGB image is captured and converted to features so it will be recognized by the camera as the target image. Printed-colored image in Fig. 2a shows the original state of the marker. The marker then will be converted into gray scale using image processing to gray-scale format as shown in Fig. 2b before it is being processed as image target in the form of features as shown in Fig. 2c. The features were recognized by the system as a unique identification. The system will detect the marker and register the marker with a virtual element. The virtual cube, for example, will appear on the top of the marker after the camera recognizes the marker. The AR user interface was using this tracking process to display animation on the top of pop-up book. The edges of real pop-up book are being converted into features for this project.

Phase 4: Developing Hand Gesture Interaction

This phase focuses on exploring the gesture interaction for the user to interact with AR pop-up book. The study of the pop-up book concept and its interactivity processes has been carried out in Phase 3. In order to enhance the realism in AR environment for conventional pop-up book, we merge the AR pop-up book with the live character, and the story elements of the pop-up book come alive. The character will follow user's hand movement, and the story elements will activate the animation effects once user's hands touch them. To actualize this realism effects, user interaction is crucial to precisely hit the characters. To look more natural, the user can use their bare hands to directly contact with the virtual elements.

Therefore, hand gesture recognition method is one of the crucial parts in this project as it acts as the input metaphor for the user to interact with the virtual object in AR environment. Sensor-based



Interactive Augmented Reality Pop-Up Book with Natural Gesture Interaction for Handheld, Fig. 3 Hand gesture recognition method

tracking device, leap motion, allows the application to read depth data and is able to track the position of user's hand in real world and mapping it into the virtual world (Guna et al. 2014). 3D hand skeleton-based interaction uses a leap motion sensor attached in front or back of a mobile device to provide simultaneous manipulations of 3D AR objects. By capturing the hand skeleton and identifying 3D finger positions and orientations, we can support a more natural hand gesture-based interaction in an AR scene. In addition to the 3D translation-only tasks in the previous works, simultaneous 3D translation and 3D rotation are possible to alter the location, pose, and size of virtual objects with hand gestures. As shown in Fig. 3, sensor-based tracking device, leap motion, allows the application to read depth data during recognition. Then, the device produces positions and orientations. It runs to track the position of user's hand in real world and to map it into the virtual world. To display virtual hand skeleton, the modeling process is required, and to enable interaction cues, the rigid body was applied to the 3D model of virtual hands. Once this process was completed, the gesture inputs are created.

Natural Gesture Interaction

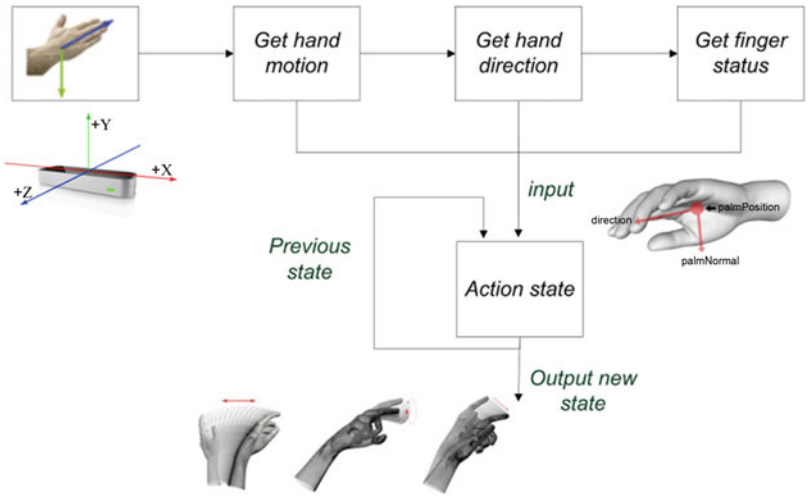
This section explains on natural gesture interaction which was divided into the following process.

Phase 1: Acquiring Gesture Inputs

There are three gesture inputs that have been defined such as TouchGesture, SwipeGesture, and CircleGesture. TouchGesture represents a virtual object that will call an appropriate animation as a feedback once it is being touched. SwipeGesture represents a virtual object that is being swiped, while CircleGesture is being retrieved and updated whenever user performed a circling gesture at designated position in the AR environment and call appropriate animation.

Figure 4 shows the flow of acquiring gesture inputs. The process starts when a leap motion device detects the hand interaction from the user using the sensor, and the gestures are identified in the pose detection. Then, the signal is sent to start the skeleton calibration that later leads to skeleton tracking. In this project, gestures used are grabbing to grasp object, pointing to select menu, palm up gesture to activate menu, and pinch to rescale the 3D object. The next process is to develop the natural gesture to interact with virtual object in AR pop-up book. In the next section, the real hand human gestures were captured by leap motion device, and recognition process was executed to obtain depth data from leap motion sensor-based tracking system.

The SwipeGesture is a gesture input where the user swipes their index finger to interact with the virtual object of the AR environment. The gesture is defined in this particular project by calculating the velocity and speed of the tip of the index finger

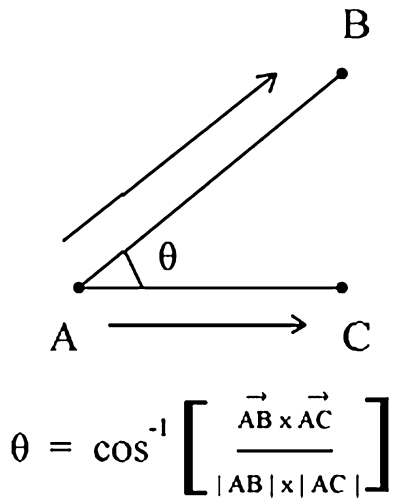


Interactive Augmented Reality Pop-Up Book with Natural Gesture Interaction for Handheld, Fig. 4 Flow of acquiring gesture inputs

and the collision detection between the finger and the virtual object that can be interacted with.

The CircleGesture is a gesture input where the user makes a circling gesture by using their index finger to enable certain features in the AR environment in order to interact with the virtual object. The gesture is defined by calculating the vector, magnitude, and angle of the circle based on the position of the tip of the index finger of the user. Figure 5 is executed to calculate the angle.

The TouchGesture is a gesture input where the user touches the virtual object by using their index finger to enable certain features in the AR environment and interact with the virtual object. The gesture is defined in this particular project by making collision detection whenever the tip of the index finger collider of the user collides with the interactable virtual object in the AR environment.



Interactive Augmented Reality Pop-Up Book with Natural Gesture Interaction for Handheld, Fig. 5 Flow of acquiring gesture inputs

Phase 2: Integrating Gesture with Handheld AR

In this phase, the gesture interaction technique is then integrated with the handheld AR scene. The hand gesture interaction technique has been developed for the user to interact with the AR pop-up book. In order to transmit the signal from the leap motion gesture tracking device to the application, we need to use Internet protocol. To actualize this, we enable the multiplayer networking as shown in Fig. 6. The network protocol in PUN (Photon Unity Networking) (Network 2015) is used, so we can send and receive gesture inputs to the AR handheld application.

Through the PUN network protocol that is being implemented in this stage, the user hand tracking data (position and rotation) from the real world is being sent by desktop (sender) to the handheld device (client or receiver). Photon network always uses a master server and one or more game servers. The master server manages the currently available games and does matchmaking. Once a room is found or created,

the actual gameplay is done on a game server. All servers run on dedicated machines.

Phase 3: Executing Gesture Interaction in AR Pop-Up Book

The leap motion is attached at the back of the smartphone, and the leap motion needs to be triggered and well-connected. It is necessary to enable the hand tracking and gesture interaction. Gesture recognition can be achieved by using the leap motion controller. It detects the hand gesture or hand signal as shown in Fig. 7. The hand gesture in the real world is recognized by the controller as shown in Fig. 7a, while the hand gesture in the virtual world is produced as shown in Fig. 7b.

The virtual hand is the representative of the real hand. Each gesture that is detected by the leap motion sensor can be seen in the monitor. Thus, every hand gesture such as swiping, pinching, or pointing in the real world is replaced by the virtual hand. This is done to ease the system development and give the user an immersive feeling or realism. Handheld device captures the user's bare hand to work with real hand gesture in handheld AR scene as presented in Fig. 8.

The handheld device's camera has synchronized the video input (720 HD pixel resolutions, 25 frames per second). It was placed in single alignment with the physical pop-up book (image of the marker) and the leap motion device which is attached to the handheld device (Android

Samsung), respectively, to detect the user's real hand skeleton as shown in Fig. 9a. A handheld screen displayed the viewing of AR scene. On the top of the table, the pop-up book was demonstrated with the user's fingertip as a controller to get the reference point of the augmentation as presented in Fig. 9b.

Problems and Restriction

The AR pop-up book is demonstrated in this entry as an interactive AR environment that enables users to play with the storytelling. The gesture interaction provides the user to directly interact with the virtual objects. The user feels more

Interactive Augmented Reality Pop-Up Book with Natural Gesture Interaction for Handheld, Fig. 8 Gesture signal transferred to handheld device

realistic to interact with 3D objects using their bare hands, and the realism of the 3D objects appears on the top of the pop-up book in the real world. Hence, there are several problems that arise regarding the real-time 3D gesture sensing in AR pop-up book. The first problem is the accuracy of the hand's detection because when the hands move into a certain position, it loses the accuracy. Accuracy in tracking is vital to ensure intuitive user interaction with the virtual elements (Lv et al. 2015). The second problem is that the user feels detached from the AR environment because of the indirect interaction method. However, these problems still persist especially when involving the precision of the hand's detection which can cause problem in the performance. It is natural that collision between the human hand and the augmented object can occur when manipulating the virtual 3D object. In AR, however, the collision happened between a virtual object and a real object; thus, the collision detection approach may be different compared with the ways in the real world. In the user's observation, with a handheld, the screens are often restricted and sometimes can be rotated between portrait and landscape. Handheld is small enough to hold and operate in the hand; nevertheless the user cannot use their both hands since the other hand needs to hold the device.

Based on the development stages described in the previous section, the standard guidelines emphasize on developing the handheld AR interface for AR pop-up book application that applies natural gesture interaction instead of touchscreen. The AR pop-up book development is explained in this entry but does not study the education pedagogy and the development stresses on AR technology to bring the physical book into more appealing and interesting handheld AR application. On the physical book, the virtual environment was overlaid in real time. The study on education purposes can be further explored the potentials and future work. Also, more future work in user's interaction for usability aspect can be carried out such as invoking the multimodal interaction that may bring AR pop-up book to be more interactive when speech input complements the gesture. Multimodal interaction is seen to advance interaction technique in AR which can improve user's experience in AR (Ismail and Sunar 2014; Piumsomboon et al. 2014). Handheld AR has been widely used with smart and portable device in the applications such as education, games, visual experience, and information visualization. However, most of the handheld applications have used touch-based to interact. Subsequently, the real hand gesture tracking in handheld AR is explored to examine how it tracks user's hands in real time. This entry describes the gesture interaction that allows the user to directly interact with the virtual objects. Thus, the user feels more realistic to interact with 3D objects using their bare hands.

Interactive Augmented Reality to Support Education

YanXiang Zhang and QingQing Zhao
Department of Communication of Science and Technology, University of Science and Technology of China, Hefei, Anhui, China

Synonyms

Augmented reality; Human-computer interaction

Definition

Augmented reality is a technology adding virtual objects to real environment through which enabling the fusion of missing information in real life. More formally, AR has been defined as a system that fulfills three characteristics (Azuma 1997). First, it combines the real and virtual world. Second, it allows real-time interaction. Third, it aligns real objects or places and digital information in 3D.

Introduction

Augmented reality has the potential to change how people interact and experience their surrounding environment (Sommerauer and Muller 2014). It is well known that interaction in education could result in better learning effect. Active involvement in learning, in the sense of being engaged, interacting, and taking part, is central to its effectiveness. To this end, a variety of computer-based activities have been developed with the aim of augmenting and extending active learning.

Nowadays augmented reality technology is emerging rapidly in educational and presentational area, such as augmented reality books, mixed reality books, AR contents in exhibitions, and AR applications in different disciplines, classroom, and laboratory. Usually, these contents will be used in classroom or in exhibition with multiple users at the same time and who usually have different background; so it is important to provide the users with a friendly, stable, and low-cost interface.

In these circumstances, tangible interface (Billinghurst et al. 2005)-based interaction for augmented reality could be a good choice.

Therefore, in this paper, authors combs the literature research related to AR support education and focuses on the combination of interactive AR and education in a variety of technical mean;, it is excepted that there could be a general interpretation of the application of interactive AR in education.

The Educational Research on AR-Supported Education

In 2010, Johnson et al. proposed AR technology as a key educational technology for the next 5 years (Johnson et al. 2010).

Santoso, Yan, and Gook from the Institute of Ambient Intelligence (IAI) work together with Sungsan Elementary School (SES) by developing a digital edutainment content based on Tangram toy as an existed edutainment media (Santoso et al. 2012).

Researchers also considered the AR technology to be integrated in the physical classroom environment (Bujak et al. 2013) and proposed AR design principles for classroom (Cuendet et al. 2013).

In 2014, Mhd Wael Bazzaza, Buti Al Delail, and M. Jamal Zemerly describes in their paper how an immersive augmented reality (iAR) application in conjunction with a book can act as a new smart learning method by engaging as many of the user's senses and human functions as possible (Bazzaza et al. 2014).

Through the applications of augmented reality, users can interact with virtual objects that are interposed on real scenes around them and obtain the most natural and genuine human–computer interaction experience (Cai et al. 2014).

In 2015, Murat Akçayır and other collaborators investigated the effects of the use of augmented reality (AR) technologies in science laboratories on university students' laboratory skills and attitudes toward laboratories (Clark et al. 2011). In 2016, Tien-Chi Huang, Chia-Chen Chen, and Yu-Wen Chou, based on Kolb's experiential learning theory, they develop an eco-discovery AR-based learning model (EDALM) which is implemented in an eco-discovery AR-based learning system (EDALS) (Huang et al. 2016).

Application of AR Technology in Different Disciplines

Many researches and developments had been made to apply AR technology in different disciplines; in this section, some applications were presented.

1. In a chemistry course

   Su Cai, Xu Wang, and Feng-Kuang Chiang, the three researchers, designed and developed a set of inquiry-based augmented reality learning tools. Students could control, combine, and interact with a 3D model of microparticles using markers and conduct a series of inquiry-based experiments (Cai et al. 2014).
2. Botany

   Based on Kolb's experiential learning theory, Huang et al. develop an eco-discovery AR-based learning model (EDALM) which is implemented in an eco-discovery AR-based learning system (EDALS). In a field experiment at a botanical garden, 21 middle school students constitute three groups participated in a learning activity using different learning types and media (Huang et al. 2016).
3. Mathematics

   In 2014, Peter Sommerauer and Oliver Müller designed and conducted a pretest–posttest crossover field experiment with 101 participants at a mathematics exhibition to measure the effect of AR on acquiring and retaining mathematical knowledge in an informal learning environment. They hypothesized that visitors acquire more knowledge from augmented exhibits than from exhibits without AR (Sommerauer and Muller 2014).
4. Biology and Medical Science

   In 2012, Tang and Ou carried out an experiment using AR and mobile technologies as an assistant tool for learning butterfly ecology (Tarng et al. 2013).

   Sylvain Bernhardt et al. proposed a new approach to automatically register the reconstruction from an intraoperative CT acquisition with the static endoscopic view, by locating the endoscope tip in the volume data (Bernhardt et al. 2014).
5. Painting Appreciation

   Kuo-En Chang et al. designed an augmented reality auxiliary tool for painting appreciation. It's a mobile guide system that

integrates art appreciation instruction with augmented reality (AR) that was designed as an auxiliary tool for painting appreciation. After the experiment, they made the discovery that most of the visitors using the mobile AR-guide system elicited positive responses and acceptance attitudes (Clark and Dünser 2012). In 2016, an AR app for iOS named ARart could turn figures in painting works into animating portraits with vividly expression and posture.

6. Early Childhood Education

   In 2015, Rabia M. Yilmaz developed educational magic toys (EMT) with augmented reality technology. EMT has included puzzles, flash cards, and match cards to teach animals, fruits, vegetables, vehicles, objects, professions, colors, numbers, and shapes for children 5–6 years of age in early childhood education (Yilmaz 2016).

7. Physical Spaces

   Sara Price and Yvonne Rogers described an approach for developing digitally augmented physical spaces. They claim that getting children to interact with the physical world, resulting in relevant augmented digital information appearing and which can subsequently be interacted with, is what can facilitate active learning (Price and Rogers 2004).

8. History and Archeology

   Martín, Díaz, Cáceres, Gago, and Gibert presented an educational application called EnredaMadrid to cope with this complexity. The objective of EnredaMadrid is to teach the history of the city in the seventeenth century to students in the activity through previous online training and a later physical technological gymkhana (Martin et al. 2011).

   Ardito, Buono, Costabile, Lanzilotti, and Piccinno presented a MAR game called Explore! with the aim to support during a visit and explorations of middle school students to archeological sites in Italy. Huizenga, Admiraal, Akkerman, and Dam have conducted a research by integrating the MAR games called Frequency 1550. This hybrid reality game was developed by the Waag Society to facilitate children to gain historical knowledge about Medieval Amsterdam (Nincareana et al. 2013).

9. Language

   Rose and Billinghurst (1995), Barreira et al. (2012), Miyosawa et al. (2012), and Li, S. and Chen, Y. (2015) developed AR tools for teaching Japanese and English language to non-native speakers.

Interfaces and Interactions in AR for Education

Image/Marker Recognition Based e-Books

Augmented Reality Books

Mark Billinghurst introduced augmented books resembling print books except that their pages have virtual graphics superimposed on them. The virtual content can provide an animated scene that complements print content and, in some cases, supports simple interactivity (Billinghurst and Dunser 2012).

Mixed Reality Book

Raphael Grasset, Andreas Dunser, and Mark Billinghurst focused creating a mixed reality book based on an already published book. With a *mixed reality book*, they propose to combine and seamlessly merge physical and virtual content in more meaningful ways. The representation of content can be either real or virtual or a mixture of both (Grasset et al. 2007).

Adrian Clark and Andreas Dünser present a new experience utilizing augmented reality-enhanced books. Users are able to color in the pages, and these pages are then recognized by the system and used to produce three-dimensional scenes and textured models reflecting the artwork created by the users. This three-dimensional virtual content is then overlaid on the real book pages, providing a three-dimensional experience using the users own content (Clark et al. 2011).

Multi-Marker-Based Interaction

Different from the single marker-based AR, the multi-marker-based AR could allow marks to

cooperate or interact with each other, one of which can be used as a trigger, when it is scanned, can trigger some interactive behavior, or can be used for experiment or game.

Su Cai, Xu Wang, and Feng-Kuang Chiang use the position of markers to present different phase of a structure and various combinations of atoms. The markers' behavior can be consistent with real particle behaviors in some cases while inconsistent in other cases. For example, when two markers get closer, a new molecule can be formulated, which is what really happens in microworld (Cai et al. 2014).

Zhang et al. (2017) developed tangible user interface elements based on multi-marker recognition for a scientific educational AR book, including virtual buttons, virtual rotate, and virtual hotspot. The user elements were integrated into various kinds of digital presentation systems by optimizing the logistic structure and interaction design of the user interface system to realize convenient spatial interactions.

The Markerless AR

Tai-Wei Kao and Huang-Chia Shih developed a markerless augmented reality (AR) applying for the picture books. They used the scale-invariant feature transform (SIFT) (Zhao and Ngo 2013; Zhao and Ngo 2013) to realize the markerless augmented reality application.

In order to reach the markerless mechanism, they identify the image contours using the point-matching algorithm: scale-invariant feature transform (SIFT) to deal with the black rectangular framing. The ARtoolkit is used to recognize the object from database and fetch the animations of the corresponding 3D objects. We collect images from the Internet to build the database and extract the SIFT features in advance (Kao and Shih 2013).

Mobile Device-Based Interactive AR for Education

Due to the rising popularity of mobile devices globally, the widespread use of AR on mobile devices such as smartphones and tablets has become a growing phenomenon (Nincarean et al. 2013).

Head-Mounted Displays (HMDs)

Head-mounted display is a kind of display which is worn on the head or as part of a helmet. It has a small display optic in front of one or each eye (Kesim and Ozarslan 2012).

In 2007, Arvanitis, Petrou, Knight, Savas, Sotiriou, and Gargalakos developed a project that is CONNECT; the CONNECT concept required student to wear a head-mounted display (HMD) and related computer-mediated learning platform in order to visualize and interact physically and intellectually with learning environment that deals with instructional materials, through "hands on" experimentation and "minds on" reflection. In addition, student can also perform experiments that are not possible in school. To evaluate the usability and effectiveness of the CONNECT project, a study has been conducted with learners with physical disabilities (Arvanitis et al. 2009).

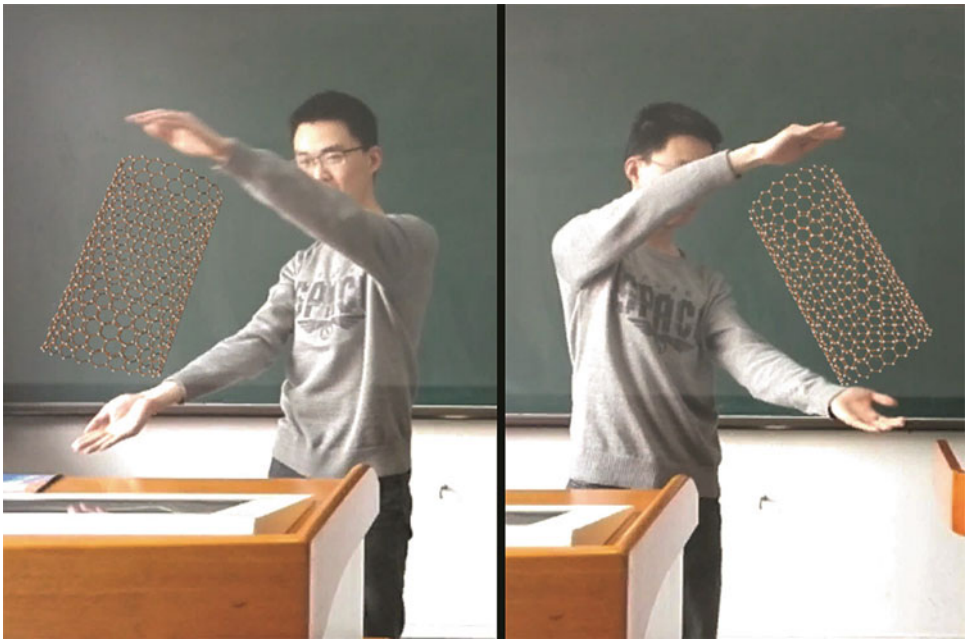
Handheld Displays

In 2009, Dunleavy, Dede, and Mitchell designed Alien Contact!, a MAR game that focus to teach math, language arts, and scientific literacy skills to middle and high school students. Alien Contact! was designed based on Massachusetts state standards and nurtures multiple higher-order thinking skills. When the students move around to their spot fields by using the Alien Contact! (Nincarean et al. 2013).

Location-Based Educational AR

The location-based AR systems use the position data of mobile devices, determined by the Global Positioning System (GPS) or WiFi-based positioning systems. The location-based AR systems enable users moving around with mobile devices in the real environment. Users can observe computer-generated information on the screens of mobile devices, while the information is triggered by the current location of the users in an environment.

CityViewAR is an example of unique experiential learning. Students can use this mobile phone application to walk through the city of Christchurch and "see" buildings as they were



Interactive Augmented Reality to Support Education, Fig. 1 Gesture-based interaction for classroom teaching (Source: Zhang and Zhu (2016). With permission from Springer)

before the 2011 earthquake made it necessary to demolish them.

Interact with Virtual Objects by Gesture

It will also be very wonderful to allow teacher to interact with virtual objects spatially, which could bring much more real feel and deeper immersive experience to the students also for the teacher.

Gesture-Based Interaction

It provides the teachers with a more effective way to communicating knowledge to the students by allowing the teachers to present the educational 3D contents interactively with spatial AR technology (Bimber and Raskar 2005). In this scenario, 3D virtual objects is displayed on a transparent projection screen that arranged in front of the podium, while students will see their teacher is interacting with the 3D virtual objects just like in the air, so the students could get much deeper immersive experience than that in traditional mode.

Zhang and Zhu (2016) build interaction between Kinect skeleton and virtual objects, which allow teacher to interact with virtual objects on transparent screen by using his hands or feet and achieve highly attractive performance. Figure 1 shows the process of a user interacting with a virtual object, zoom in or zoom out, move, and rotate them. Here, different gestures will be used to realize different manipulations.

Tangible Augmented Reality (TAR)

Tangible augmented reality (TAR) technology opens a novel realm which integrates the computer-generated elements into the real word. Its applications into design education have been explored with a limitation to this entire area (Chen and Wang 2008). In TAR systems, markers/tags can be added to the text to identify information related to the descriptions in the text and are detected with an image-processing tool, such as ARToolkit (Kato et al. 2000).

In 2008, Rui Chen and Xiangyu Wang presented and evaluated one TAR system to improve the pedagogical effectiveness of experiential and collaborative learning process in urban design education. For TAR systems, the initial mental image/model can be gained from reflective observation

(AR) and tactilely from tangible feedback (tangible interface) (Chen and Wang 2008). Chien-Huan Chien, Chien-Hsu Chen, and Tay Sheng Jeng had also applied TAR in their study; they aim to use augmented reality (AR) technology to create an interactive learning system, which helps medical students to understand and memorize the 3D anatomy structure easily with tangible augmented reality support (Chien et al. 2010).

Mark Billinghurst had enumerated the relevant examples in his paper:

> "Young children often fantasize about being swallowed up into the pages of a fairy tale and becoming part of the story. The MagicBook makes this fantasy a reality by using a normal book as the main interface object. People can turn the pages of the book, look at the pictures, and read the text without any additional technology. However, if they look at the pages through a handheld Augmented Reality display, they see three dimensional virtual models appearing out of the pages. The models appear attached to the real page, so users can see the AR scene from any perspective simply by moving themselves or the book." (Billinghurst et al. 2001b)

Interactive and Collaborative Education by AR

In natural face-to-face collaboration, people use speech, gesture, gaze, and nonverbal cues to attempt to communicate. In many cases, the surrounding physical world and objects also play an important role, particularly in design and spatial collaboration tasks (Billinghurst and Kato 2002). In a study by Bressler and Bodzin (Bressler and Bodzin 2013), middle school students collaboratively played an inquiry-based mobile AR game by using mobile devices to scan QR (quick response) codes to access game-related information, solve a detective case, and learn forensic science. The study reported that the group play of the vision-based AR game can increase students' science interest and their collaboration skills.

With the development of AR technology, it often be used to "shared space" system as a face-to-face collaboration tool, and it can be used to support remote collaboration, as well as the multiscale collaboration.

Face-to-Face Collaboration by AR

AR interfaces blend the physical and virtual worlds so real objects can interact with 3D digital content and improve users' shared understanding (Billinghurst and Kato 2002).

Hannes Kaufmann and Dieter Schmalstieg created various hybrid hardware setups, in order to complement the diverse teacher–student interaction scenarios for educational environments, and it was used in classroom. The wearable AR kits are composed of back pack computer, stereoscopic see-through head-mounted display with camera, and custom pinch gloves for two-handed input. One kit can be worn by the teacher, and the second one is available for use by students. In addition, it is intended to be used by high school students and teachers in an interactive, collaborative manner and to blend seamlessly into an everyday classroom situation (Kaufmann and Schmalstieg 2003).

Remote Collaboration by AR

AR technology can also be used to support remote collaboration. Mark Billinghurst and Hirokazu Kato, in an AR conferencing interface they developed in 1998, demonstrated a user that wore a lightweight HMD (with camera) and could see a virtual image of a remote collaborator attached to a physical card as a life-size, live virtual video window.

Multiscale Collaboration by AR

AR techniques can also be used to support multiscale collaboration, where users collaboratively view a data set from different viewpoints. Mark Billinghurst and Hirokazu Kato explored this in their MagicBook work (Billinghurst et al. 2001a). Individual users of the MagicBook interface have their own independent view of the content; any number of people can view and interact with a virtual model as easily as they interact with a real object (Billinghurst and Kato 2002).

Conclusion and Discussion

In this paper, the authors summarized the applications of AR technology in the field of education and tried to give an outline of the support and influence of interactive AR on education.

With the rapid development of AR technology and the popularization of AR device, AR could bring very wide space for education, the possibilities of AR interactions for education will be explored more and more, and also the utilization of AR in different disciplines will be deeper and deeper.

However, compared to other more mature technologies that were applied in education, it is still not so easy to use AR in education; AR creation usually needs many technical abilities such as programming and 3D modeling and more, but it is very difficult for normal teachers to utilize so many technologies, while programmers are usually not familiar with educational contents and the needs of interaction design from educational principles. So an excellent AR educational application should be the result of convergence team works of teachers, educational researchers, and technical experts and programmers.

Interactive Computer Graphics and Model-View-Controller Architecture

Aaron Hitchcock and Kelvin Sung

Synonyms

Model-view-controller (MVC); MVC architecture; MVC design pattern

Definition

Interactive graphics applications are a class of application that allows users to interactively update their internal states. These applications provide real-time visualization of their internal states with computer graphics. The model-view-controller (MVC) architecture is effective for presenting, discussing, understanding, and implementing this type of application.

As illustrated in Fig. 1, the **Model** contains the application state, the **View** renders the model graphically, and the **Controller** modifies the model. A **User** interacts with the MVC system by observing the content of the view and manipulating the controller to alter the state of the application.

Implementation Considerations

The model defines the persistent application state and implements interface functions which allow it to be modified. The model implementation should be independent from the technologies that build the view and controller components. For example,

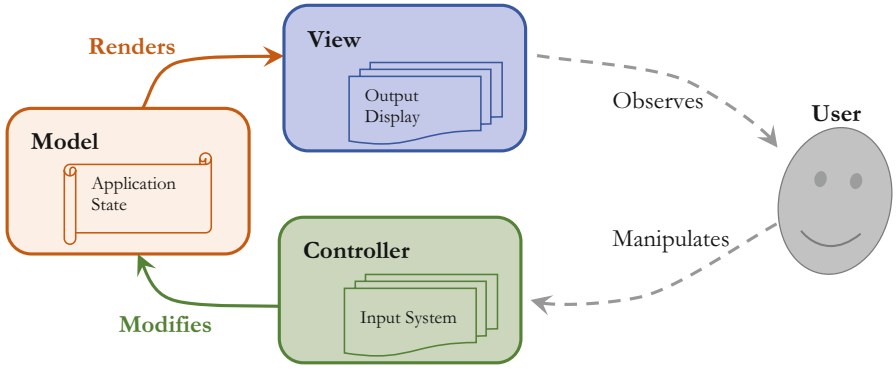
the model of an image editing application should consist only of data structures and algorithms for defining and maintaining the abstract content of images. In this way, different views and controllers based on distinct libraries can be defined and implemented for the same model. For example, view/controller implementations for a PC-version and a Mac-version are based on the same model.

One important benefit of the MVC architecture is the clear enforcement of separation between state modification and visualization. During state modification, the controller receives user input and triggers the model to modify the application state. The MVC architecture ensures that the application state rendering is a completely separate process involving the model triggering the view. During this visualization stage, the application state should be read-only and should not be changed.

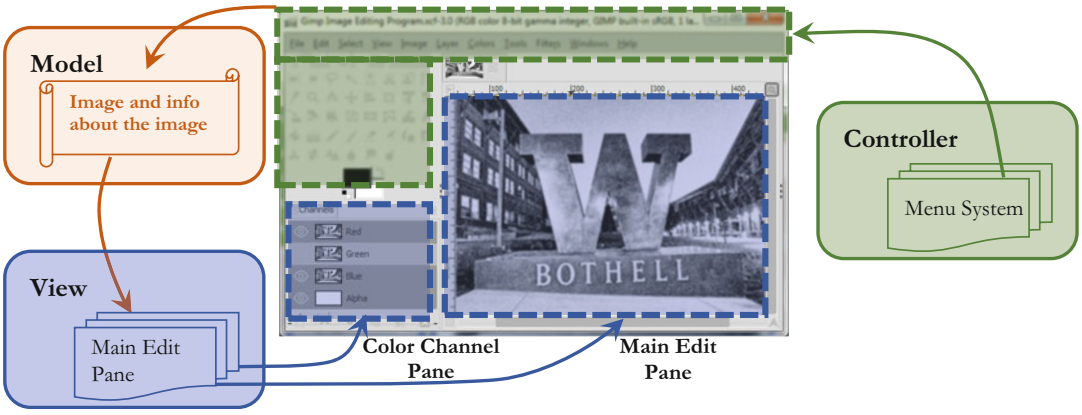
Figure 2 illustrates understanding GIMP, an image editor, as an MVC application. In this case, the Model (in orange), or the application state, is simply the image and information about the image. The view (in blue) renders and visualizes the application state as different panes in the application window, and the controller (in green) provides the interface for the user to manipulate and update the image.

Context of Video Games

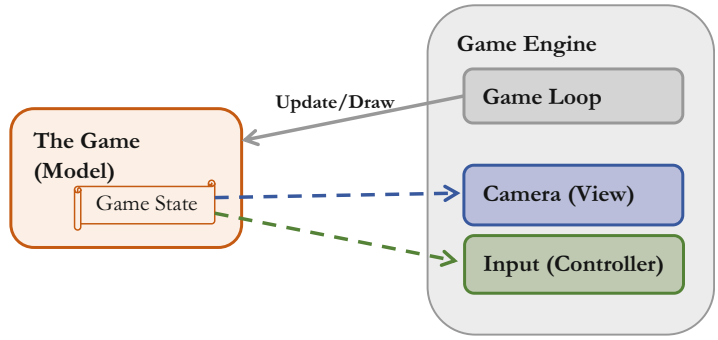
Modern video games are examples of interactive graphical applications. Typically, games are built based on specific game engines. As illustrated in



Interactive Computer Graphics and Model-View-Controller Architecture, Fig. 1 The model-view-controller architecture



Interactive Computer Graphics and Model-View-Controller Architecture, Fig. 2 GIMP (an image editor) as an example MVC application



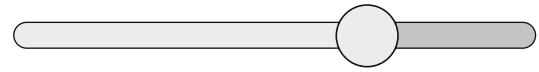
Interactive Computer Graphics and Model-View-Controller Architecture, Fig. 3 Modern video games and the MVC architecture

Fig. 3, the game loop sub-system in the game engine periodically triggers the game to update and draw its state. In response, the game invokes the game engine functionality: the camera sub-system to render, and input sub-system to receive user commands. In this way, the game is the model responsible for defining and maintaining the game state, and the view and controller functionality are provided by the game engine.

Considering a video game as an MVC application ensures the separation of state update and draw operations. Game state should only be modified during the game engine update call, and only rendered during the game engine draw call. As discussed in the game loop implementation, the update and draw call frequencies are typically independent and can vary with the underlying system performance. Any attempts to draw the game state during update cycles or change the game state during draw cycles can easily result in a chaotic and unmanageable system.

Applying the MVC

It is interesting that the MVC architecture can be applied to interactive graphical systems of any scale. For example, the slider bar shown in Fig. 4 is a fully functional graphical interactive system. In this case, the model is a numeric value (typically a floating-point number), the view presents the numeric value to the user, and the controller allows the user to interactively modify the value. A typical view draws icons (bar and knobs) representing the range and current value in the model, whereas the



Interactive Computer Graphics and Model-View-Controller Architecture, Fig. 4 A Unity3D slider bar

controller typically supports mouse down and drag events to interactively modify the value in the model component. A slider bar implementation can choose to include an additional view by echoing the numeric value in a separate textbox. The corresponding controller would allow the user to modify the numeric value in the textbox. When the typing functionality is disabled, the view exists without a corresponding controller.

Definition

Although interactive systems already exist in the animation industry, nowadays there is not a system that combines an animated story and a virtual reality system complemented by the spectator's interaction, in order to tell that story properly.

Introduction

Over the years, animation has had a great impact on society. It has been used to entertain, but also to inspire, inform, and educate. In the last century, animation has been transformed in terms of finding new ways to achieve it. The use of new technologies has provided entirely new forms to appreciate this art form, such as computer animation, digital art, and virtual reality, among others.

Thus, the main objective of this project is to create an animated story that will use a CAVE, a holographic projection, and a tracking system as necessary tools to tell the story and not only as a way to project it. With the use of this technology, we are seeking to generate a similar or a better cinema-like viewing experience for the users.

In this entry, we will introduce the prototype of the first phase of our investigation. This small-scale prototype simulates the performance explained above. The goal is to test the response of the users to this prototype.

Brief Description of the Project

CAVE

A CAVE system is built using three different screens. Through the use of stereo glasses, the user is introduced to a three-dimensional environment.

Hologram

A light source originated from the top of the CAVE illuminates a contained reflective object. The diffraction generated from the interaction between the light and the object produces a computer-generated 3D holographic animation.

Tracking System

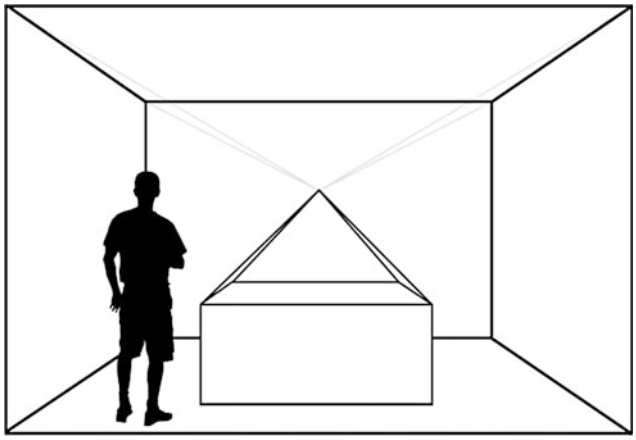
A tracking system captures the user's movement. The gestures generated with this system stimulate and put in action the holographic animation and the graphic elements inside the CAVE environment (Fig. 1).

The possibilities of how a story can be told are infinite, since there are lots of combinations that can be done between the use of the CAVE, the hologram, and the user's interaction.

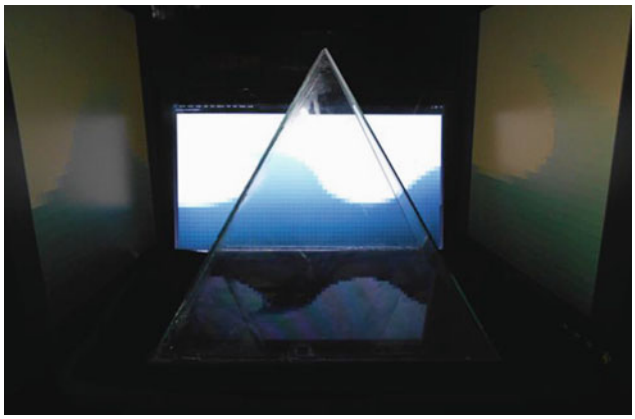
Description of the Prototype

The following elements were used in the creation of this prototype in order to simulate the performance of the project:

Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology,
Fig. 1 Diagram that illustrates the project



Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology,
Fig. 2 CAVE prototype



Three 18.5″ * 11.6″ Monitors

These monitors are used to simulate the CAVE (Fig. 2).

One 18.5″ * 11.6″ Monitor

This monitor is used as a light source above the CAVE to project the hologram.

Reflection System

A reflective pyramid used to simulate the holographic projection (Fig. 3).

A Leap Motion Controller

Used to track the user's gestures.

Overview

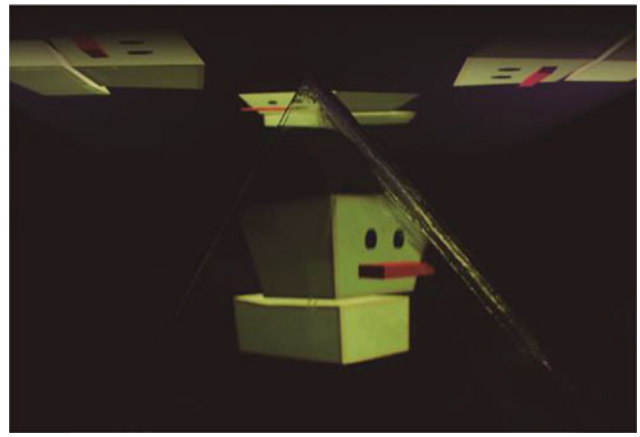
For this prototype we designed a Unity project. In this project there is a 3D model of an animal and an interactive voxelized environment (Fig. 4).

When the user makes a movement with his hand, the leap motion catches it and both, the animal and the environment, answer with an animation. The animal moves in its individual way according to which animal is being used (duck, firefly, or elephant). The user can change the animal by making another gesture. Since each animal has its unique voxelized environment, when the animal is changed, also thus the environment (Fig. 5).

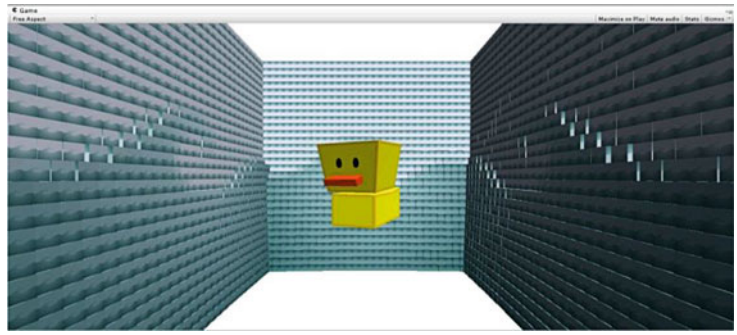
Experiments and Results

Fifty people tested the prototype (18–40 years).

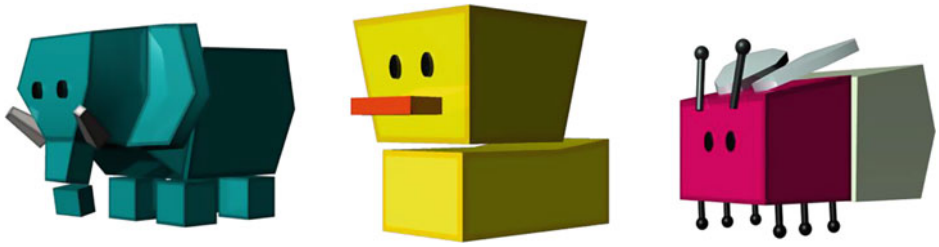
The obtained results were very positive in terms of interaction and entertainment.



Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology, Fig. 3 Holographic projection



Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology, Fig. 4 The Unity project

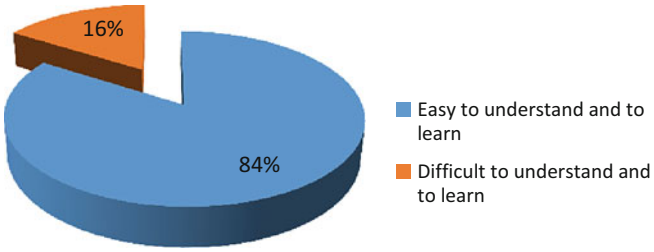


Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology, Fig. 5 Models used for the prototype

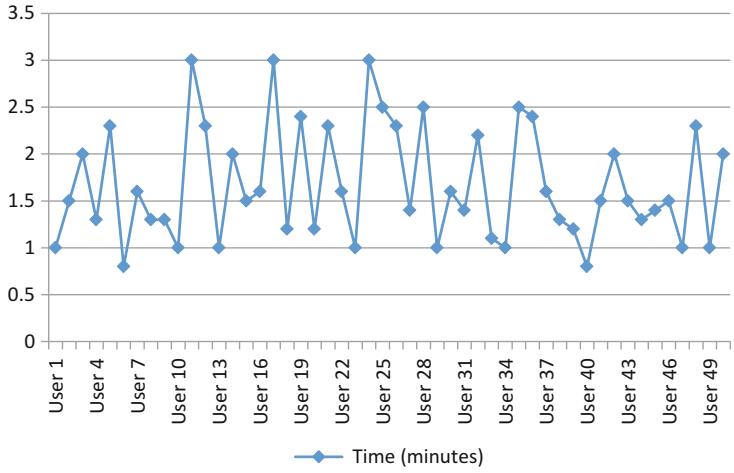
Ninety-five percent of the testers liked to be the directors of the actions that were projected in the CAVE (Fig. 6).

Eighty-five percent of the testers expressed that the interaction system was easy to understand and to learn (Figs. 7 and 8).

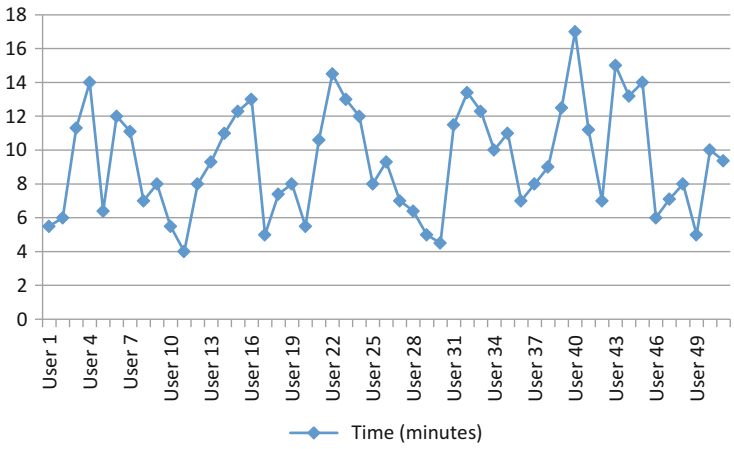
The average time that testers took to understand the functioning of the holographic and CAVE system was 1.67 min. Moreover, users were allowed to interact with the prototype for as long as they liked, and the average time was 9.3 min.



Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology, Fig. 6 Interactive design graph



Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology, Fig. 7 Time used to understand the system graphic



Interactive Virtual Reality Navigation Using Cave Automatic Virtual Environment Technology, Fig. 8 Time that users liked to interact with the prototype

Eighty percent of the testers considered that the aspects of the prototype that could be improved are the number of actions that the user can make. This change would increase the possible stories or results, giving an illusion closer to the role of a storyteller.

Data indicates that the system was an easy one to understand and followed the interactive design; and very importantly, it proved to be entertaining for them.

Further Work

To create a whole animated story that uses the holographic projection and the CAVE in its narrative structure, then test the simulation with a real holographic projection in a real-scale CAVE with several users at the same time. This test will include:

- How the animated story functions in this platform
- User's response
- Different and new ways in which users could interact, since there will be several of them

Conclusion and Discussion

The use of new technologies can contribute a lot to storytelling. They provide to the artists different perspectives of how to push an animated project, in order to come up with more interactive and interesting results.

Definition

An Internet Protocol Version 6 (IPv6) is the most recent generation of Internet Protocol.

An Intrusion Detection System (IDS) is a device or software application that monitors a network for malicious activity or policy violations.

A Network Intrusion Detection Systems (NIDS) is a system that analyzes incoming network traffic.

Introduction

Our world has become a big network where everyone connects to it by the Internet. Most people living on the earth rely on this network. They are reading news, transferring money, and checking their emails and much more in their daily basic life. The goal of the new modern world is the availability, integrity, and confidentiality of this network. The rapid growth and widespread use of electronic devices and data processing (cloud computing, web application, Internet network, wireless networks, and private network) will raise the need for a solution that can provide a safe and secure infrastructure for a safe communication. To use the Internet, each device needs to have an Internet Protocol (IP) address. An IP address is a unique number that is assigned to every device that is connected to the network or Internet. The IP address enables devices to communicate with each other. There are two different versions of IPs, Internet Protocol Version 4 (IPv4) and Internet Protocol Version 6 (IPv6). IPv4 was developed in the early 1980s, but because of the rapid growth of the Internet, IPv4 has been fully allocated to Internet Services Providers and Internet users, and then there was a shortage of IPv4 available address (Icann 2011). IPv6 was standardized in 1996 to replace the current version of IPv4 and covers the biggest limitation of IPv4 which is the lack of enough addresses for all Internet users. In recent years, the major service providers have started to offer IPv6 addresses to their users (Icann 2011). Based on a report from Google on 16 Aug 2018, 23.91% of the users that access Google are over IPv6. This report shows how usage of IPv6 has grown during the last couple of years. With IP being the Internet's main protocol, many constitutive Internet technologies are heavily tied to it and the change to version 6 resulted in updates of related protocols (Fig. 1).

The major changes between IPv4 and IPv6 can described as:

- **IPv6 large address:**

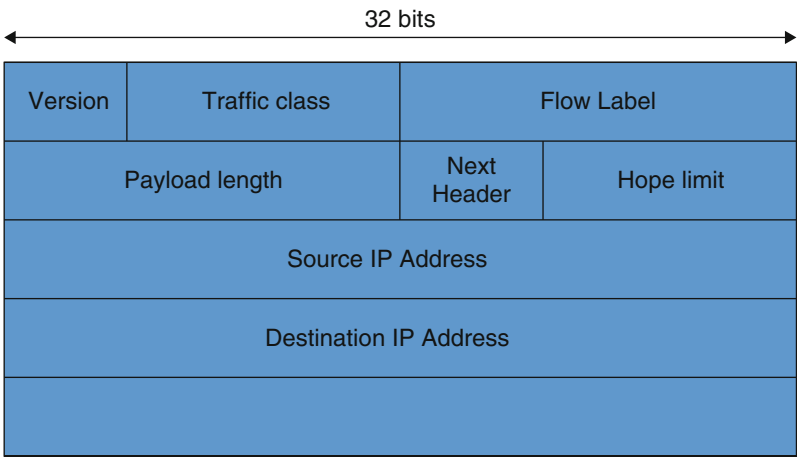
IPv6 is 128bit, this mean, it can provide 340 trillion, trillion, trillion IPv6 addresses. That means IPv6 uses 128bit address space.

- **IPv6 fragmentation:**

IPv6 is no longer required to be fragmented by the router. All fragmentation and reassembly are performed by sender and receiver host(s).

- **Addressing:**

IPv6 uses three types of addresses which are unicast, multicast, and anycast. Unicast is only assigned to a single node of IPv6; however, a



IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games, Fig. 1 IPv6 header

multicast is assigned to multiple nodes in a single multicast group.

- **Auto-configuration:**

New capabilities of IPv6 that allow a new node automatically configure IP addresses.

- **Extension headers:**

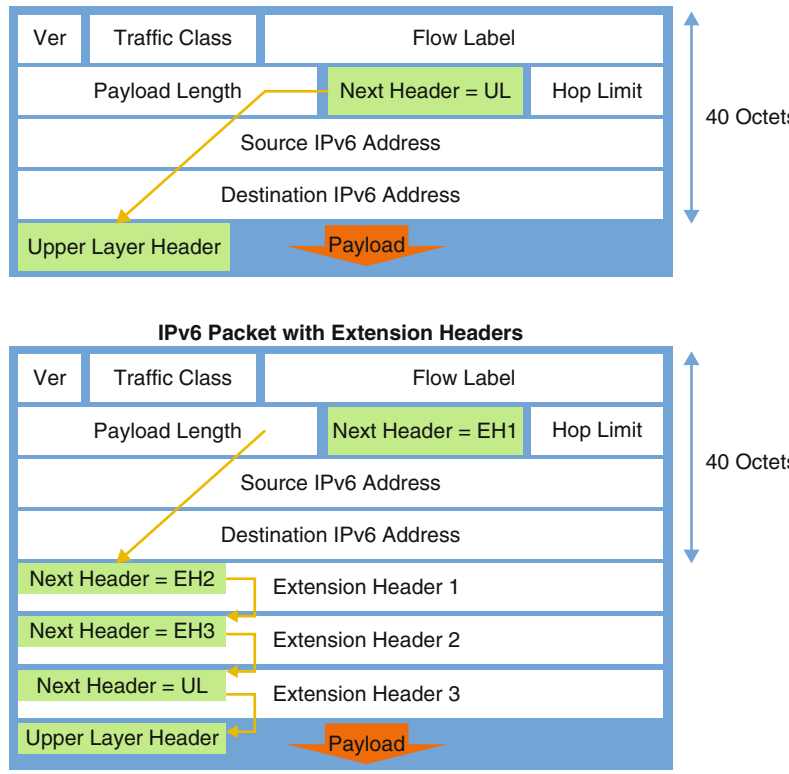
Referring to RFC 2460 (Deering and Hinden 1998), a full implementation must include support for six extension headers, which are Hop-by-Hop Options, Routing (Type 0), Fragment, Destination Options, Authentication Headers, and Encapsulating Security Payload.

Extension Headers

Apart from expanded addressing capabilities, one of the most important and significant changes in IPv6 is the improvement of supporting extension header with the options (Deering and Hinden1998). In IPv4, some of the header fields have been dropped to reduce the cost of packet handling and processing. However, this has been changed in IPv6 where the Extension Headers function is added. The Extension Headers are placed between IPv6 header and the upper layer header in a packet, and each of the Extension Headers is identified by a distinct next header value. As this is an optional field, each IPv6 packet can have zero, one, or more extension headers. Each Extension Headers have multiple of 8 octets long Fig. 2.

Internet Control Message Protocol Version 6 (ICMPv6)

Unlike ICMP for IPv4, ICMP for IPv6 (Conta and Deering 2006) play an important role in IPv6 network. ICMPv4 is not required in IPv4, but ICMPv6 is a required element and therefore it cannot be filtered completely. ICMPv6 has a next header value of 58. The main reason that ICMP was developed as a protocol was to be used for tests and diagnosis on IPv4 networks. The most important features that ICMP provides are to enable the utilities such as ping and trace



IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games, Fig. 2 IPv6 packet with extension header

route to help verify end-to-end IP communication and connectivity and provide information about any errors on the connection back to nodes (Davies and Mohacsi 2007). ICMPv6 messages can be categorized into two categories (Davies and Mohacsi 2007):

Error messages:

- 1 Destination Unreachable
- 2 Packet Too Big
- 3 Time Exceeded
- 4 Parameter Problem
- 100 Private experimentation
- 101 Private experimentation
- 127 Reserved for expansion of ICMPv6 error messages

Informational messages:

- 128 Echo Request
- 29 Echo Reply

Error messages will generate a report of any errors that occur during the message delivery. Informational messages will allow sharing of required information between nodes. As in other features, attackers may use ICMP for exploitation, and therefore sys-admin has no choice but to completely filter the protocol to prevent such attacks (DoS/DDoS, Evasion, Scan, Man in the Middle) (Davies and Mohacsi 2007). However, unlike ICMPv4, ICMPv6 cannot be filtered/blocked completely due to the important role that it plays in the IPv6 network. According to RFC 4890, filtering ICMPv6 on routers and firewalls is different from on a host. ICMPv6 is a required protocol on every IPv6 network. ICMPv6 provides the following functions (Davies and Mohacsi 2007):

- Neighbor Discovery Protocol (NDP), Neighbor Advertisements (NA), and Neighbor Solicitations (NS) provide the IPv6 equivalent of IPv4 Address Resolution Protocol (ARP) functionality.
- Router Advertisements (RA) and Router Solicitations (RS) help nodes determine information about their LAN, such as the network prefix, the default gateway, and other information that can help them communicate.
- Echo Request and Echo Reply support the Ping6 utility.
- PMTUD determines the proper MTU size for communications.
- Multicast Listener Discovery (MLD) provides IGMP-like functionality for communicating IP multicast join and leave.
- Multicast Router Discovery (MRD) discovers multicast routers.
- Node Information Query (NIQ) shares information about nodes between nodes.
- Secure Neighbor Discovery (SEND) helps secure communications between neighbors.
- Mobile IPv6 is used for mobile communications.

Neighbor Discovery Protocol (NDP)

As defined in RFC2461, Neighbor Discovery is a protocol for IPv6. Since Address Resolution Protocol (ARP) has been removed in IPv6, both hosts and routers use Neighbor Discovery messages to determine the link layer addresses of nodes on the local link. When a host is connected to an IPv6 network, it sends Router Solicitation messages to routers on the same link to get network information such as network prefix, default router, and other network parameters. Stateless Auto-Configuration is another feature based on Neighbor Discovery Protocol which allows new hosts on the local link to get and configure their IPv6 address (Thomson and Narten 2007) (Table 1).

The transition from IPv4 to IPv6 should have eliminated any related security issue to the new protocol. The security mechanisms for network layer protocol should be examined in many different areas. One of these areas is how Operating Systems handle the IPv6 fragmented packet and how Network Intrusion Detection Systems can detect an attack on the IPv6 network. If used properly by an attacker, this feature in IPv6 can lead to Network Intrusion Detection System (NIDS) evasion, Firewall evasion, Operating System fingerprint, Network Mapping, Denial of Service (DoS)/Distributed Denial of Service (DDoS) attack, and Remote code execution attack (Ptacek and Newsham 1998; Erickson 2007; Chen 2014; Reese 2009).

IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games, Table 1 Neighbor Discovery Protocol (NDP) messages

ICMPv6 type	Message name	Source address	Receiver address	Used for
133	Router Solicitation (RS)	Nodes (routers link local address)	FF02::2 (multicast address)	Sent by hosts to locate routers on attached link
134	Router Advertisement (RA)	Routers	Sender of RS or FF02::1	Routers advertise their presence and link prefixes, MTU, and hop limits
135	Neighbor Solicitation (NS)	Nodes	Solicited node multicast address or the target node's address	To query for other nodes link layer address and also used for duplicate address detection and to verify neighbor reachability
136	Neighbor Advertisement (NA)	Nodes	In response to NS sender or to FF02::1	In response to NS query
137	Redirect	Routers	Link local address	To inform other nodes for better next hop routers

IPv6 Vulnerabilities

Despite the security improvements in IPv6, some vulnerabilities are still common between IPv4 and IPv6. Insertion, Evasion, and Denial of Service are three different categories of attacks, which were proposed by Ptacek and Newsham (1998) for the first time. Most of the vulnerabilities are common between IPv4 and IPv6 (Mali et al. 2015; Satrya et al. 2015; Tripathi and Mehtre 2013), and because of the changes that were made in the IPv6 implantation (Deering and Hinden 1998), additional vulnerabilities arise as well. There are many features which are new and unique to IPv6. One of them is the improved support of headers (extensions and options) which were not existing before in IPv4.

Insertion, Evasion, and Denial of Service are three different categories of attacks, which were proposed by Ptacek and Newsham (1998) for the first time. The aim of these attacks is to make the IDS or victim host process different data or process the same data but differently. By using an insertion attack, IDS accepts a packet(s) that is rejected by the host. The packet looks valid only to the IDS. The attacker can bypass the signature-based IDS by inserting the traffic in such way that the signature is never matched or found. This process is different in Evasion attack; in Evasion attack the IDS rejects the packet that the end host accepts. The attacker can send some or all malicious traffic into the network without being caught by the IDS.

IPv6 Fragmentation Attack

Referring to all the aforementioned (RFC2460, 1998; RFC 3964, 2004; RFC 7123, 2014) recommendations of corresponding IPv6 Requests for Comment (RFCs) and previous sections, when using IPv6 Extension Headers and IPv6 Fragmentation, there are potential attacks against the Operating System (OS). In case of discrepancies between the behavior of several OS, this can lead to OS fingerprinting, Intrusion Detection System (IDS) insertion and IDS evasion, and Firewall evasion. Furthermore, there are still some issues regarding the handling of the IPv6 fragments (Atlasis 2012). One of the simplest examples of the one of the most common attacks can be fragmentation attack, which is common between IPv4 and IPv6 (Atlasis 2017).

Several IPv6 fragmentation and overlapping methods were used to test the effectiveness of some of the most popular OS, and it is found that none of them is fully RFC compliant while most of them seem to have significant issues (Fig. 3).

IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games, Fig. 3 IPv6 fragmentation process

Operating System Fingerprint

This method is used for identification of the victim host. In human life, fingerprints can be used to identify a person. Similarly, an OS has its unique implementation of communication protocols by which it can be identified. In order to identify the OS and its version remotely and without having a direct access to that system, the attacker uses fingerprinting to analyze certain characteristic and network behavior communication (Eckstein and Atlasis 2011). By using such a method, the attacker can easily discover the live host on the network and identify their OS, and furthermore by using this method, the attacker could even reveal the victim host's missing security patches or service packs. As a result, the attacker can easily use the related vulnerability to gain access to and control the end host easily (Allen 2007).

ICMPv6 Flooding Attack

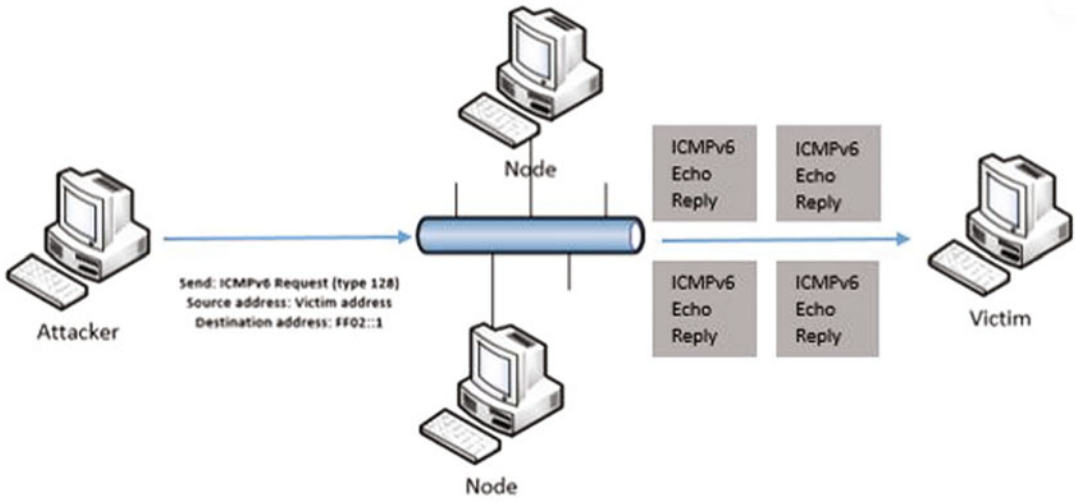
ICMPv6 flooding attack is one of the most common attacks in both IP versions. The aim of using ICMPv6 attack is to use all of a victim's resources (bandwidth, CPU, and RAM) by sending a large amount of traffic. The packet can contain any ICMPv6 type with source address referring to another node on the network (Martin and Dunn 2007).

To disturb the communications between routers and hosts, an attacker can use ICMPv6 error or informational messages such as ECHO (request and reply), Router Advertisement, Neighbor Advertisement, Neighbor Solicitation (NS), and Multicast Listener Discovery messages for a successful attack (Chen 2014).

ICMPv6 Amplification

The amplification attack is considered as one of the common security challenges in IPv4 and still exists in IPv6. The amplification attack allows the attackers to generate huge numbers of packets using a small number of packets and amplify it to a large number of packets based on the multicast address feature.

Broadcast Amplification attack also known as Smurf (Fig. 4) is the most well-known amplification attack, which is based on ICMPv6 multicast address function. The attacker uses Smurf attack to launch a DoS attack by sending an ECHO request packet to a multicast address with spoofed source address of victim machine. Once all nodes of the targeted multicast address have received a packet, all nodes start to reply to the source, which is the victim, and flood it with a large number of ECHO reply attacks. The victim will be overwhelmed and cannot respond to genuine requests (Martin and Dunn 2007). In addition, there is another version of Smurf attack which is called rSmurf (Remote Smurf) attack that has stronger amplification, because each packet generated by



IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games, Fig. 4 Smurf attack

rsmurf6 can generate a large number of packets on the remote LAN. As a result, one malicious packet will generate a storm of traffic on victim network.

ICMPv6 Protocol Exploitation

By sending a Router Advertisement (RA) packet, any node on a network can claim that they are a router. An attacker can use this feature of ICMPv6 to perform a Man in the Middle (MitM) attack by presenting themselves as a router. The first method an attacker can use to launch a Dos/DDoS attack is by using Router Discovery packets, which are Router Solicitation (ICMPv6 type 133) and Router Advertisement (ICMPv6 134). The second method will be using Neighbor Discovery (ICMPv6 types 135 and 136) packets. The third method will be using Redirect furcation (ICMPv6 type 137) packets.

The Router Discovery process is responsible for packet routing. On the IPv6 network, a host will find a router by sending a Router Solicitation packet to router multicast address (FF02::2). Once the Router Solicitation packet is received by the default router, in response to that packet, the router will send Router Advertisement to the host. The Router Advertisement packet contains the information needed by the host such as router specification, onlink prefix, and network parameter (Tripathi and Mehtre 2013). An attacker can misuse Router Solicitation and Router Advertisement packet and perform the following attacks:

- Default router is "killed": By default, every node has a router table to list all routers on the network. When a node does not have any record in the table, it will consider that all destinations are on link (Narten et al. 2007). Now an attacker can send a Router Advertisement packet with router lifetime equal to zero and spoofed address. When the host receives the Router Advertisement packet, it will delete the router record because of the lifetime, and then it will redirect all packets to the destination without a router address. If the traffic is going outside of network, all packets will be lost, and therefore an attack has occurred (Tripathi and Mehtre 2013).
- Bogus address configuration prefix attack: As mentioned earlier, one feature of IPv6 is that in absence of DHCP server, a node will generate their own IPv6 using Stateless Auto-Configuration with subnet prefixes of Router Advertisement messages that are received from a default router (Kempf and Nordmark 2004). The router sends Router Advertisement messages

accordingly to all nodes to update their routing table information. By sending a Router Advertisement message with invalid subnet prefix to multicast address (FF02::1), an attacker can launch an attack. Now all nodes will generate an invoice IPv6 address based on the invalid prefix that was received, and all communication between hosts will be disrupted.

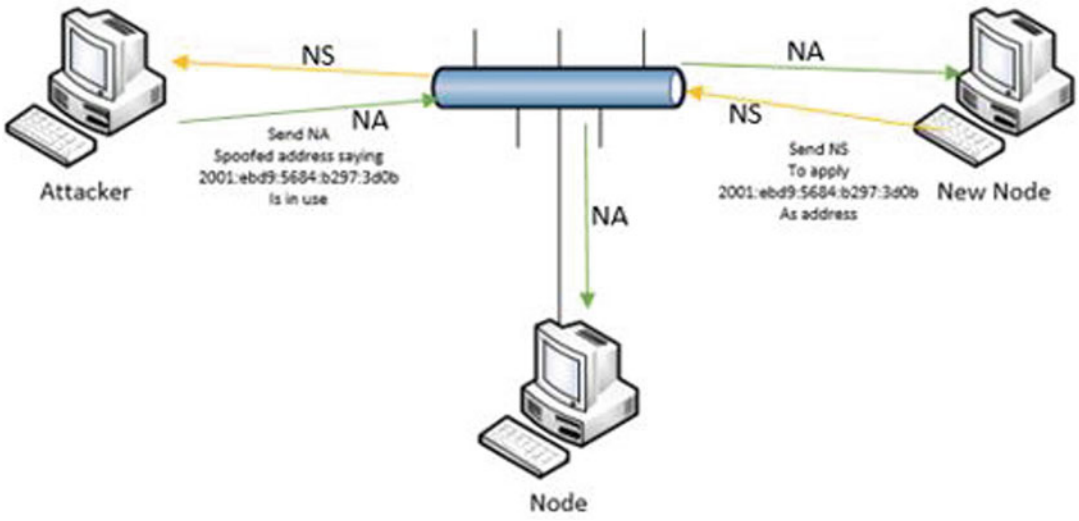
- Parameter spoofing: As mentioned earlier, Router Advertisement messages contain network parameter information, and they are very useful to the host to send IPv6 packets later. An attacker can send a Router Advertisement message (e.g., with a small hob limit), which contains false network parameters that can disturb the packet transmission and host's communications.

Neighbor Discovery Attack

Neighbor Solicitation and Neighbor Advertisement are two ICMPv6 messages that Neighbor Discovery Protocol (non-routing one) uses. Two of the most important jobs that NDP is responsible for are neighbor unreachability and Duplicate Address Detection (DAD). An attacker can use these functions as an advantage and launch an attack.

Duplicate address detection DoS attack: Another feature on IPv6 network is Duplicate Address Detection (DAD). When a node needs a new IPv6 address, it will send Neighbor Solicitation to all-nodes multicast address "FF02::1" to check whether that IP is in use or not. If the sender did not receive a reply, that means the IPv6 address is free and the new node can use it. An attacker can use this as an advantage and send a spoofed Neighbor Advertisement packet claiming that the address is in use every time that node sends a request. By using such an attack, the new nodes will not get an IPv6 address, and therefore there is not any connectivity (Fig. 5) (Zhao-Wen et al. 2007).

Neighbor Unreachability Detection failure: Neighbor Unreachability Detection (NUD) process detects when a neighbor is unreachable. Once this has happened, the node starts to send a Neighbor Solicitation packet to lost node address and waits for a Neighbor Advertisement reply for a short period. If no Neighbor Advertisement is received, the node will delete the peer node from its Neighbor Cache Entry table. An attacker can send a malicious Neighbor Advertisement reply to a Neighbor Solicitation request to show that the node is still alive and on the network which it is not.



IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games, Fig. 5 DAD attack

ICMPv6 Redirect Message Attack

IPv6 nodes use ICMPv6 "Redirect" message to find a better path to their destination. The router will send "Redirect" message to a node to optimize the packet routing process and the delivery path. The following attack types can utilize ICMPv6 redirect messages:

- The traffic can be forwarded to non-existent link.
- The traffic can be redirected to an existing node. This will result in the node being overwhelmed.

Gaming company has become more attractive targets for attackers during the last couple of years. Moving the gaming companies Internet Protocol from Version 4 to Version 6 will create some vulnerabilities which attackers can use to launch ICMPv6, DDoS, and some other malicious activities by bypassing the detection by using some of IPv6 new features such as Extension Headers and Fragmentations.

Attacking Tools

This section covers some of the most common attack tools to perform an attack on IP level.

Fragrouter is a network intrusion detection evasion toolkit developed by Dug Sing. It implements most of the attacks described in the Ptacek & Newsham in 1998. (It features a simple rule set language to delay, duplicate, drop, fragment, etc.).

THC-IPV6-ATTACK-TOOLKIT is a collection of attacking tools that can be used to test the implementation of IPv6 network and test firewall and NIDS. This collection contains the following tools (van Hauser 2008):

- parasite6: ICMPv6 neighbor solicitation/ advertisement spoofer, puts you as man-in-the middle, same as ARP mitm (and parasite)
- alive6: an effective alive scanning, which will detect all systems listening to this address
- dnsdict6: paralyzed DNS IPv6 dictionary brute forcer
- fake_router6: announce yourself as a router on the network, with the highest priority
- redir6: redirect traffic to you intelligently (man-in-the-middle) with a clever ICMPv6 redirect spoofer
- dos-new-ip6: detect new IPv6 devices and tell them that their chosen IP collides on the network (DOS)

Havij is an automated SQL injection tool that takes advantage of a vulnerable web application to find and exploit SQL injection vulnerabilities. An attacker can perform back-end database fingerprint, DBMS login names and password hashes, and much more like fetching data from a database. However, this tool is capable of accessing the underlying file system and executing the operating system shell commands.

Acunetix is a web vulnerability scanner designed to replicate a hacker's methodology to find vulnerabilities like SQL injection and DoS/DDOS attack. By using Acunetix you can use an extensive feature set of both automated and manual penetration testing tools, security analysis and repair detected threats.

Mendax is a TCP de-synchronizer that injects overlapping segments in randomly generated order. An attacker can use Mendax to evade NIDS. Mendax is not a router, but is a standalone TCP client program which can be used by an attacker to perform an evasion from an input text file, performs a fixed set of evasion technique, and sends restructured exploit to the victim host (Gorton and Champion 2003).

In Table 2 a summary of Evasion and Insertion attack tools is provided.

Related Work

Alnakhalny et al. (Saad et al. 2014) proposed a detection method for ICMPV6 flood attack based on Dynamic Evolving Neural Fuzzy Inference System (DENFIS). DENFIS is a system that uses online clustering to perform online and offline learning. The proposed system is based on self-machine learning. However, one important question here is if the attacker uses a mixture of method to bypass the detection, it will take time for the machine to learn that algorithm and detect future attack. Because of that, attackers will

IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games, Table 2 Evasion and Insertion attack tools

Tools name	Developer(s)	Evasion attack
Fragrouter	Dug sing	Most techniques described by Ptacek & Newsham

Havij	IT Sec team	SQL injection and web app evasion
Acunetix	Acunetix team	Web app analyser and evasion test attack
Mendax	Min G. Kang	TCP overlapping

change their method, and therefore the detection method could not be useful for such attack.

Anbar et al. (Saad et al. 2016) proposed An Intelligent ICMPv6 DDoS Flooding attack Detection Framework (v6IIDS) Using Backpropagation Neural Network. Their aim is to detect ICMPv6 Flooding attack using an Intelligent Intrusion Detection System in an IPv6 Network (v6IIDS). The proposed system detection has four processes. These processes are data collection and pre-processing, traffic analysis, anomaly-based detection, and ICMPv6 flooding detection.

Rafiee et al. (Rafiee and Meinel 2013) proposed a new algorithm to tackle the issue with Cryptographically Generated Addresses (CGA) [3972] and Privacy Extension [4941] in IPv6 state-less configuration. The proposed method uses a new way to generate Interface Identifier (IID) to reduce the computing cost and prevent security theatres related to state-less configuration such as IP spoofing. However, it seems the proposed algorithm cannot detect Duplicated Address Detection attack on IPv6.

Kent et al. (Kent and Seo 2005) provided Security Architecture for the Internet Protocol. In IPv6 unlike IPv4, Internet Protocol Security (IPSec) is mandatory. IPSec draws a line between protected and unprotected interfaces for host or network. If traffic want to cross the boundary, they are subject to the access control list that is specified by the system admin who is responsible for IPSec configuration. These controls indicate whether packets cross the boundary unimpeded, are afforded security services via AH or ESP, or are discarded.

IPSec provide an end-to-end security between end hosts and all intermediate nodes. IPsec has the following weaknesses (Yang et al. 2010; Arkko and Nikander 2005):

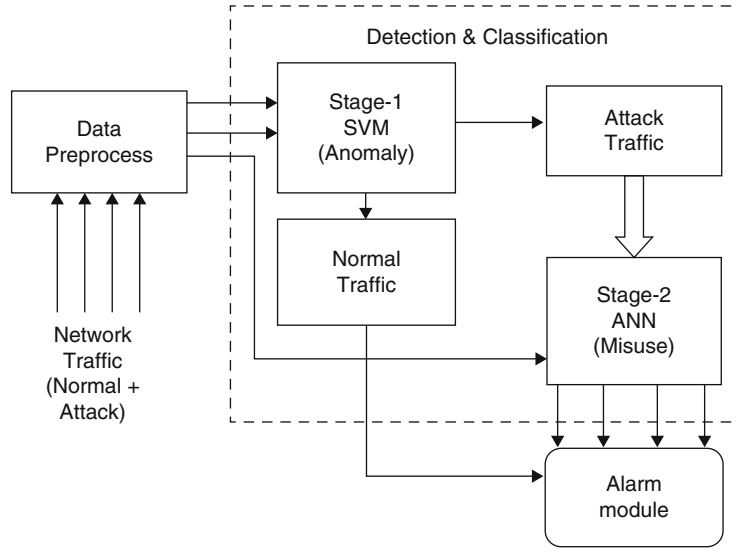
- Not support the upper layer
- Because it needs key exchange, it will use IKE management, which requires a valid IPv6 address. So it cannot work when a new host joins a network and therefore is not able to protect Network Discovery Protocol.

Because of the complex configuration, most of the users do not implement IPsec for link local addresses.

Kempf et al. (Kempf et al. 2005) proposed SEcure Neighbor Discovery (SEND) protocol to mitigate the issue of IPsec for link local commination. SEND is an extension of NDP that adds several options such as Cryptographically Generated Addresses (CGA), RSA Signature and Timestamp, and Nonce Options. In addition, they introduce four new Authorization Delegation Discovery, Certification Path Solicitation Message Format, Certification Path Advertisement Message Format, Router Authorization Certificate Profile and Suitability of Standard Identity Certificates (Kempf et al. 2005; Securing IPv6 2002).

A review of SEND done by Meinel et al. (Alsa'Deh and Meinel 2012). They are challenging SEND as it is not provided link layer security and cover NDP communication confidentiality. The Cryptographically Generated Addresses cannot assure the real node identity. Because of the structure of SEND, it will use more CPU of nodes and bandwidth to process. In addition, if Router Authorization and Standard Identity Certificates implement into routers, It will put an extra workload on them.

Hussain et al. (Hussain et al. 2016) proposed a two-stage hybrid classification (Fig. 6) method using Support Vector Machine (SVM) as anomaly detection in the first stage and Artificial Neural Network (ANN) as misuse detection in the



IPv6 Common Security Vulnerabilities and Tools: Overview of IPv6 with Respect to Online Games, Fig. 6 Two-stage hybrid classification with SVM and ANN (Hussain et al. 2016)

second. The advantages of using SVM and ANN are better classification accuracy and a low probability of false positive. The proposed system classifies the type of attack into four classes: Denial of Service (DOS), Remote to Local (R2L), User to Root (U2R), and Probe. The first stage is looking for any abnormal activities that could be an intrusion, while the second stage does the future analysis, and if there are any known attacks, it will classify them into the four categories that were already mentioned.

Data Preprocess will prepare and pre-process network traffic in the data pre-process module. Once data has been received and pre-processed, it will be sent to the next process, which is "Detection and Classification." The detection and classification process has two stages: NIDS using SVM for anomaly and ANN for misuse detection. The data then passes to the Alarm module, which interprets event results on both stages and reports the intrusion detection activity.

Conclusion

IPv6 introduces new features and capabilities. These results in new issues, and security issues is one of the most important among them. Most of the vulnerabilities are common between IPv4 and IPv6, and because of the changes that were made in the IPv6 implantation, additional vulnerabilities arise as well. There are many features which are new and unique to IPv6. One of them is the improved support of headers (extensions and options) which were not existing before in IPv4.This entry reviewed an overview of Internet Protocol Version 6 (IPv6), IPv6 new features, and some of the most common vulnerabilities; also, a review was discussed for existing solutions and how those solutions can mitigate the vulnerability discussed in this entry. By adopting IPv6, gaming industries will become an attractive target for attackers to launch an attack such as ICMPv6 and DDoS to game companies. These sorts of attacks already launched to Sony, EA, and Steam really affected the gaming industry in terms of availability. In addition, the customer data on gaming companies could be in danger, as attackers could use IPv6 new features to bypass the detection on NIDSs and do malicious activities on gaming server.

Definitions

Indie game: short for independent game, a game typically created by a small team of developers without the financial or labor backing of major production/publication studios.

Indie developer: short for independent developer studio, a team of game developers working without assistance from major production/publication studios.

Introduction

Itch.io is a web-based video game publishing platform built specifically for early indie/learning developers. Originally released in 2013 by *Leaf Corcoran*, the platform has become rapidly more popular among a niche community of developers within the wider gaming industry, as of the most recent public report (Hayes 2019) hosting over 200,000 games, with rough estimates that the platform likely hosts 250,000–300,000 games at the time of writing (October, 2020), based on community estimates on daily uploads. The platform gears itself toward new developers by an especially low barrier to enter publishing games, providing accessible access too and hosting game jams, providing development tools, and regularly publishing information on blogs that are geared toward starting indie developers.

History

Prior to its creation, the original concept for *Itch.io* was to create an online interface for making a customizable video game page where indie developers could quickly post their content online for the world to see. However, the service expanded both prior to, and in the early years of the website. These services continued to expand as the community of the site gained prominence within the indie development community.

By 2015, *Itch.io* has grown to a more dedicated and well-established indie development platform, with support for both participating in and hosting game jams, dedicated servers to dealing with issues, communities following developers, or indie groups on the site; at the time, they hosted over 15,000 games and applications, according to their released site statistics. Similarly, in early 2016, the official release of the *Itch App* created a desktop application interface for the previously solely web-based site.

From 2016 onward, a great effort to expand, polish, and enhance existing services and platforms can be seen, much of which can be seen by the enhancing of their desktop application and expansion of their community on their site, including additions in customization options for game pages and analytics for developer postings.

User Interaction

Users of *Itch.io* largely approach the platform from at least one of the following purposes:

The user is...

1. A developer looking to publish games
2. A developer looking for game development tools
3. A developer looking to participate in game jams
4. A gamer looking to play indie games
5. A company/group looking to host/sponsor a game jam

Most of the traffic of the site is geared toward the publication and purchasing/downloading of games, points 1 and 4, respectively. Though the game jam services are also an especially notable portion of the site (Vu and Bezemer 2020), and according to released *Itch.io* statistics, they attract a large portion of new users to the site. This has been especially true recently, with the top 5 game jams (2 from 2020, 2 from 2019, and 1 from 2018), accounting for a cumulative total of over 45,000 individuals/teams registering for the events and over 10,500 games added to the site.

Playing Games on Itch.io

Many games on *Itch.io* are entirely free to play or follow the "pay what you want" model of sales, though the platform does allow for developers to have a set costs for games. Additionally, with the added ability to play HTML5 games in their respective web browser, users do not even necessarily have to log in to play some of the games on the platform. However, for access to the vast majority of the library, a user will need to sign up for a free account and download a game from a given page.

A majority of games on the platform seem to be set to the "pay what you want" model, which a small portion of users regularly donating money to the developers of games they enjoy, and users are also given the ability follow and interact with developers on forums on the game's respective page or within the sites' social forum directly. Once a user has downloaded a game on itch.io, they permanently have access to that game and any new editions that come out of it, though it is not uncommon for developers of paid game projects to post a game's alpha, beta, demo, or any other marketing materials as a separate posting from the finalized product to avoid giving away their game for free.

Publishing Games on Itch.io

As *Itch.io*'s original conceptualization was based around the concept of game publishers, one can still see this reflected in the site's available publication and developer features. Posting a game on *Itch.io* is free, with no limitations on the quantity of products you can post or the quality of posting options. Customization for game and developer pages is built into the site, and a developer can, without opening any other application or knowing how to code, do the following:

- Post on forums
- Change the page stylizations
- Add or edit content of the game/developer page
- Add dev logs
- Change settings or pay models of the page
- View game analytics
- Get embeds for websites or social media
- Have a handful of other useful features

The number of available free features, and general pro-indie/new developer attitude of the community, has led to itch.io gaining many of its developers. Additionally, *Itch.io* regularly posts on forums and developer communities with indie developer strategies for designing, developing, publishing, and marketing new indie games.

Itch.io as a Political Institution

Itch.io, being an American company, has both officially and unofficially taken a number of political stances regarding political issues in the USA. The most notable of these events is the support the platform has given for the NAACP and the Black Lives Matters movement, where the platform raised over eight Million dollars in June of 2020 in response to the George Floyd Protests throughout the USA (Statt 2020). This money was raised

by creating a purchasable indie game bundle of games created by African American artists or that strongly featured socio political discussions of race and racial intolerance. This stance generated a small amount of political backlash from parts of the *Itch.io* community but was largely praised both within and without the *Itch.io* community and drew many artists to the site for the first time (Squirrelrampage 2020).

Itch.io and Steam

The expansion of the video game market, especially within the past decade after the economic recovery of the 2008 global recession, has seen a dramatic rise in digital publication platforms as one of, if not the most common, the ways for purchasing and obtaining video games, for both PC and console games. Its most notable competitor, and the largest market share for publication and distribution of digital games then, both indie and otherwise, is of course *Steam*, the publication platform owned by *Valve Corporation*.

Steam also hosts a very large indie community and has significantly greater universal brand recognition. However, *Steam* has a notably higher bar for the posting and sale of games, with developers needing to be formally recognized and signing legal paperwork before joining and paying $100 as a starting fee and then for each additional game they look to post on the platform. This has caused many developers to view itch as somewhat of a "starter platform" where they first go to develop their skills, before producing games that are profitable enough to then warrant the posting on *Steam* (Maiberg 2015).

Definitions

Augmented reality (AR) augments real world with virtualized contents (i.e., objects and/or supporting information) which appears to coexist in the same space as the real world (Palmarini et al. 2018). Its predecessor, i.e., virtual reality (VR), on the contrary, generates a completely artificial environment of the reality.

Key Early Verticals for Augmented Reality

Although the promising notions of AR and VR were coined several decades ago, the technologies enabling AR have just recently converged to a critical point enabling people to enjoy its experiences and to fully reap its benefits (Yuan 2017). AR is believed to be one of the key technology enablers for Industry 4.0 and is anticipated to disruptively change our world in many aspects. This section briefly depicts the key early verticals of AR in numerous industrial sectors, i.e., manufacturing, healthcare, logistics, design and architecture, military, and data centers (Syberfeldt and Gustavsso 2017; Chandler 2017) along with their salient characteristics.

Manufacturing: Connected devices and wearable products have rapidly penetrated across the manufacturing industry, hence opening new doors for innovative AR experiences. AR is currently making rapid strides in numerous areas. It is used

for the monitoring and solving of pain points experienced on the shop floors, i.e., pain points along with key performance indicators (KPIs) could be directly projected to the engineers and maintenance teams in order to analyze and resolve the issues in real time. This is also efficient in case of production downtime due to a broken part of a machine, as teams equipped with AR capabilities can quickly respond to the hardware problems in almost no time. AR could further assist the production teams in the physical asset-based logistics and status of the physical stock on the shop floor, and the same can be superimposed in the form of digital content to augment the real-time views (Caricato et al. 2014; Uva et al. 2018; Chang et al. 2017).

Healthcare: Healthcare is one of the most dominant sectors impacted by AR in numerous ways, i.e., from training medical students about the human anatomy to counseling mothers struggling with breastfeeding by effectively allowing the counselors to *see through* the eyes of mothers via an AR wearable device, to assisting the patients to accurately describe their past and existing medical conditions to their doctors, to enabling nurses to locate human veins conveniently during intravenous injections, to facilitating the curious consumers of the pharmaceutical industry with the 3D views of drug actions and effects in the human body, to practicing minimally invasive surgeries by enabling the surgeons to *see through* the patient (without the need for opening them up) during the surgical planning and image-guided surgery, etc. (Herron 2016; Chen et al. 2017).

Logistics: One of the biggest waves of change anticipated in logistics industry is in the form of AR technology, i.e., in the warehouse operations, wherein, notion of *pick-by-vision* for providing a hands-free digital approach could be employed instead of a slow and error-prone *pick-by-paper* approach in order to optimize picking process (the software employed for *pick-by-vision* could have features like the barcode reading, indoor navigation, real-time object recognition, seamless integration with centralized warehouse management systems, etc.), in the warehouse planning to accommodate a number of value-added services by visualizing rearrangements by incorporating digital representations of envisaged future settings in the current warehouse environment, and in the freight transportation as loaders could have access to the real-time digital data about the next pallet to be loaded and its placement in the vehicle along with the pertinent loading instructions thus saving the tedious process of paper-based cargo lists and speeding up the freight loading process (Stoltz et al. 2017; Glockner et al. 2014).

Design and Architecture: Over the past few decades, one of the key challenges confronting designers was to dive deep into physical space of a structure or an object that they are conceiving. Traditionally, 3D objects were conceived over the 2D screens. However, as of late, more meaningful and lucrative ways have transpired and AR experiences undoubtedly lies at heart of the same, i.e., from the powerful 3D printing facilitating the companies and firms to rapidly transform their concepts into implementation thus ultimately leading to reduction in costs and securing of more clients to a collaborative design process for sourcing of innovative ideas, variants, and its feedbacks from the geographically distributed consumers during the product's planning stage, to equipping the architectural project teams and their clients to immerse in an interactive AR experience for monitoring progress of ongoing projects via a real-time digital modeling of a construction site, thus avoiding the tedious task of walking clients on the construction sites and preventing any unwanted accidents, to the spatial augmented reality revolutionizing the automotive industry by enabling the designers to assess curves and geometries more efficaciously by projecting virtual data on a real vehicle model during its development process (i.e., typical virtual data is often being displayed on monitors and its size is often scaled down and is not a precise reflection of the reality), etc. (Chi et al. 2013; Elia et al. 2016; Behzadan et al. 2015).

Military: AR has been making its stronghold in the battlefield, i.e., from projecting precise maps, navigation way points, friends or foe discrimination, and pertinent information to a soldier's field of vision, to integrating specialized AR gadgets to a weapon control system for

enhancing the mission's effectiveness, to training of the combat personnel for complex conditions arising in the battlefield through injecting of virtual threats into a realistic environment for ensuring that the troops are skilled enough to quickly respond and operate the equipment in every possible scenario, to training fighter pilots for diverse battle scenarios and certain specialized cockpit operations, i.e., aerial refueling and missile deployment, as most of their trainings are conducted over flight simulators and setting up live combat operations could be very expensive (You et al. 2018; Karlsson 2016).

Data Centers: AR is anticipated to bring tremendous benefits to data center planning and to a wide range of its operations and processes, i.e., from remote management of the data centers to spatial tours via the 3D real-time imaging superimposed with pertinent contextual information so as to have a better understanding of local prevailing circumstances, to the navigational guidance in a data center for better identification of error-prone devices or installation of a new device along with installation instructions, to the color labeling of identical-looking racks and cabinets within a datacenter to reflect status messages (i.e., notifications, alarms, or warnings) or operational analyses along with troubleshooting instructions if any, to the identification of a device and device-related specific virtual information and real-time datasets by employing the QR scanner and many more (Deffeyes 2011; Emeis et al. 2017).

Challenges and Limitations in Implementation of Augmented Reality

Despite a number of potential applications of AR in modern-day industries, there are still several challenges and limitations that hinders its true realization (Akayra and Akayra 2017; Zhang et al. 2017). Some of these challenges and limitations are discussed as follows.

Low Latency Monitoring and Tracking: In order to have an essential AR experience, it is indispensable to precisely track and subsequently monitor an individual's location, the objects and people surrounding him/her, and more interestingly, what actions are being carried out through their eyes, hands, and voice and all in few milliseconds so as to ensure that the precise contextual information gets layered on the actual environment via an AR device. Hence, the design of a state-of-the-art real sense cameras (possessing the full five-finger integration), diverse sensors, and microphones for an AR device still poses a daunting challenge yet to be fully realized.

Seamless Optical Displays: A seamless optical display blending (both) physical and digital world adds another layer of complexity in the early realization of AR. It is pertinent to note that VR is already utilizing high-resolution innovative screens, in whose production, the smartphone industry has been actively involved over the past few decades. In case of VR, the user typically glances on the screen; however, in AR, it is essential to look through the screen so as to still experience the real-world environment.

Computing Power: Power is one of the serious challenges currently being faced by the AR industry. Today, with the continuous evolution of stronger yet ever smallest processors, there would certainly be (in the near future) powerful enough processors specifically for AR. Thus, powerful processors require powerful batteries and especially with characteristics, i.e., low consumption, high capacity, and small enough to be compatible with lightweight AR wearable displays. Complexity versus implementation is an issue and balance is still to be determined.

Scaling: Interpreting (or rendering) of the digital data into meaningful graphics and subsequently scaling it down to suit the perspective of individual's visual field adds a significant challenge in the vast implementation of AR.

AR Software: One of the indispensable components of AR software is its competence to efficiently accumulate, process, and analyze potentially diverse range of inputs simultaneously and transform them accordingly based on new digital information so as to provide the high-end AR experiences. For realizing the same, high-speed connections would thus be required to tie the AR software to the back-end services, thus

ensuring the future AR-enabled devices to be the world's most capable Internet of Things (IoT) endpoints.

Conclusion

The notion of AR has grown by leaps and bounds over the past few decades, but very few of us know how far it has come in reality. At the time of writing of this article (2018), various tech giants such as *Google, Apple, Facebook*, etc., have launched their AR development kits and a new wave in technology has finally set in. Also, a number of industries have started embracing AR and specific applications are now being experienced in their initial forms. *But how big would the AR impact be?* In order to address this question, this article serves as a major reference for not only highlighting some of the key early verticals for AR in various industrial sectors but also deliberates on some of the critical challenges and limitations hindering its true realization. It is beyond any doubt that AR is soon going to be a mainstream product and either people would be wearing AR headsets for most of their time or AR would replace everything we do on smartphones, act as a new interface for laptops or desktops along with numerous specialized applications across all industrial sectors. This ultimately would lead to another revolutionary wave in the gaming industry too.

Synonyms

Fighting game; Interactive game; Video games

Definition

SNK: A Japanese video game hardware and software company.

KoF: The King of Fighters is a series of fighting games by SNK.

Introduction

The King of Fighters (KoF) is a series that started in arcades on SNK's own game system. Starting in 1994, leading up to the advent of the greatly awaited King of Fighters XV – the 15th edition in 2021, this entry goes over the history of the series, SNK, spinoffs, and other media, as well as the e-Sports scene.

The Games and Their Unique Systems

Starting off, the main set of KoF games began with the King of Fighters '94 for the Neo Geo, which was followed with yearly releases up until 2003, where SNK started taking more time to make the new editions of the game series. KoF XI released in 2005, KoF XII alongside 2002 Unlimited Match in 2009, KoF XIII in 2010, and KoF XIV in 2016 (Mendoza 2020).

The King of Fighters series differentiates itself from its peers with its 3-on-3 team battle setup. Traditionally, fighting games ask players to select a single character to use against their opponent, but in the KoF series players select a team of three characters to challenge their opponent's three characters. After one of the characters is downed, the next character in line will tag in. Characters standing in the backlines can sometimes perform support attacks to help.

Along with previously discussed mechanics, KoF employs its own set of mechanics, such as the many jump options (short hop, short jump, hyper hop, hyper jump, etc.) as well as the MAX Mode which could open up Death Combos in certain iterations. King of Fighters has no predetermined combos, and players have to make up their own using basic, unique, and special moves.

Spinoffs and Other Media

The King of Fighters have inspired spin-off titles such as the Maximum Impact series, which offered KoF in a 3D environment in 2004 (Maximum Impact), 2006 (Maximum Impact 2), and 2007 (Maximum Impact Regulation-A). Other spin-off titles include The King of Fighters '94 Re-Bout (2004), The King of Fighters Neowave (2004), The King of Fighters XI (2005), The King of

Fighters '98 Ultimate Match (2008), and The King of Fighters 2002 Unlimited Match (2009).

There are also a ton of manga for the main series from 1994 to 2000, and more recently, one for XIV. For example, *The King of Fighters: A New Beginning* is a Japanese shōnen manga authored by Kyōtarō Azuma as an adaptation of SNK's 2016 fighting game The King of Fighters XIV. There are also quite a few drama CDs as well as some animations. One of those animations is a complete retelling of KoF '94, called *The King of Fighters: Destiny*. There was also a movie adaptation *The King of Fighters* in 2010 starring Sean Faris as Kyo Kusanagi, Maggie Q as Mai Shiranui, Will Yun Lee as Iori Yagami, and Ray Park as Rugal Bernstein. However, it was none too faithful to the source material and was panned by critics and audiences alike (*The King of Fighters*).

SNK Company Turmoil

After the release of KoF 2000, SNK filed for bankruptcy in 2001 and auctioned the intellectual property rights for its franchises. This led to KoF 2001 and the original 2002 being created by a different company, called Eolith. SNK's founder and other executives founded a new company under the name Playmore later in August of 2001. In late October of the same year, Playmore had successfully reacquired the SNK intellectual property rights and began rehiring former employees.

Esports Scene

Several editions of The King of Fighters appeared in e-sports competitions. Some tournaments have used KoF '95 through '98 Ultimate Match (some as recent as 2020). Before the release of KoF XIV, the e-sports tournaments mainly featured 2002 Ultimate Match and KoF XIII. A particularly outstanding finale for one of the KoF XIII tournaments at EVO 2013 involved a 2-0 comeback followed by a reverse 3-0. However, the lack of documented e-sports tournaments for The King of Fighters makes it difficult to expound on the KoF e-sports scene.

Conclusion

The King of Fighters is a fighting game series that has existed for 27 years as of 2021, and that has survived through the bankruptcy of its game publisher SNK. Over the years, the game has run on many platforms including Neo Geo arcade, Atomiswave arcade, Taito Type X arcade, Sega Saturn, Dreamcast, PlayStation, Game Boy, Wii, Nintendo Switch, iOS, Android, Microsoft Windows, and Xbox. King of Fighters differentiates itself using its unique 3-on-3 combat and many ways to execute attacks to such a degree that it has received widespread appeal.

Kingdom Hearts (2002): An Analysis

Michael Phillips[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Action role-playing game; Hack-n-slash

Definitions

Action role-playing game	It is a specific type of role-playing game where the player controls a character engaged in real-time combat.
Hack-n-slash	A type of combat that focuses on quick, hand-to-hand or melee weapon combat.

Kingdom Hearts (2002)

Kingdom Hearts is a single-player, action role-playing game that is a crossover between two companies and their universes. These two companies consisted of Square Enix (originally known as just Square) and Disney Interactive. Square Enix and Disney Interactive Studios were the major developers and publishers, but the series itself has also had help from other companies to compile the game together. Kingdom Hearts resides within its own series (Kingdom Hearts) and spans over nine main games. Kingdom Hearts was first created on its own in-house engine, Luminous Engine, but with the release of Kingdom Hearts 3, the game will be switching over to Unreal Engine 4. Kingdom Hearts was a PlayStation 2 exclusive, released on March 28, 2002. The player takes on the role of the main protagonist, Sora. Kingdom Hearts is rated as E, but as the series progressed, the ESRB rating has change to E 10+ (Entertainment Software Ratings Board).

Kingdom Hearts follows the story of a boy, Sora, who sets off on an adventure after his home, Destiny Islands, is consumed by Darkness. Throughout the series of the games the player gets to watch Sora grow as a hero. In the original game he arrives in Traverse Town and meets a new set of friends, Donald and Goofy, and then sets off to find Riku, Kairi, and King Mickey. His relationship with every friend he meets enables his growth to flourish throughout the story. The trio meets many heroes and villains spanning across both the Disney and Final Fantasy universes. Since Kingdom Hearts consists of both Disney and Square Enix characters, they wanted to attract both hardcore and casual players. They were able to create a game that could bring together people from all ages, young or old, to enjoy this series of games. Kingdom Hearts managed to secure the spot for the 10th best-selling PlayStation 2 game of all time as well (Game Enthusiast).

Kingdom Hearts took much influence from Square's Final Fantasy franchise, and it consists of a hack-n-slash approach to its gameplay. The main objective was to travel around defeating bosses to advance to different worlds. The player controls Sora with the ability to use basic attacks, special attacks, magic, and in some cases, dodges. Meanwhile, Donald, Goofy, and/or another character who can replace the two will assist Sora within battles. The player can also control the behavior of the assisting characters to a certain extent. Sora's stats are based around his level, and the game in its entirety is set around an experience point system. Defeating enemies is the only way to earn experience points which in turn increases Sora's level (capping at 100). Kingdom Hearts is relatively linear; the player moves from world to world defeating Heartless, bosses, etc., but the player also has the chance to run into short side-quests to secure items, experience, etc. Among all these systems set in place, the combat interface seems to be the simplest. There is a command bar consisting of Attack, Magic, Items, and Specials. Lastly, there is a health bar and magic bar, as well as both of the assisting character's health and magic bars.

Kingdom Hearts was a one of kind collaboration, which was perceived rather impactfully in the public's eyes. Due to its massive success, Kingdom Hearts never had any controversies surrounding the series. At first, no one thought Disney and Final Fantasy would be a good combination but were proven wrong. The original characters, especially Sora, were unique because the player could witness how their personalities grew and altered throughout the stories of each of the nine games. Kingdom Hearts made the 21st

spot on IGN's top 25 PS2 games of all time. IGN had this to say, "The premise behind the game was completely absurd: Disney cartoon characters like Mickey Mouse thrown in with Square Enix characters to make a new kind of action RPG. However, as strange as it sounds, these two dissimilar franchises came together incredibly well" (IGN). The characters – original, Disney, and Final Fantasy – helped develop the game into such a hit as it is still today. Kingdom Hearts suffers from linear progression but not in an unplayable manner. Kingdom Hearts has not really changed up its graphical capabilities over the years, but here is a YouTube video showcasing the evolution of the series: https://www.youtube.com/watch?v=Wu-QQgWeCi4.

As stated earlier, Kingdom Hearts managed to secure the spot for the 10th best-selling PlayStation 2 game of all time as well (Game Enthusiast). Kingdom Hearts had such a unique way of going about its gameplay, but it could be comparable to games like the "Tales of" series, the "Persona" series, and of course the "Final Fantasy" series.

Lattice Boltzmann Method for Diffusion-Reaction Problems

Sicilia Ferreira Judice
Faculty of Technical Education State of Rio de Janeiro, FAETERJ Petropolis, Petropolis, Brazil

Synonyms

Cellular automata; Diffusion-reaction problems; LBM; Numerical methods

Definitions

- Cellular automata
  A mathematical model based on simple and local rules capable of generating complex behaviors.
- LBM
  Lattice Boltzmann method, a numerical method based on kinetic equations formulated on a mesoscopic scale.
- LGCA
  Lattice gas cellular automata, a specific cellular automaton, whose proposal is to simulate fluids using simple and local rules that imitate a particle dynamics.

Introduction

The lattice Boltzmann method (LBM) is based on the fundamental idea of constructing simplified kinetic models that incorporate the essential physics of the microscopic processes, so that the estimated properties satisfy the macroscopic equations. LBM is especially useful for modeling complex boundary conditions and multiphase interfaces (Chen and Doolen 1998). Extensions of this method are described in the literature, including simulations of turbulent fluids, suspended fluids, and diffusion-reaction systems (Wei et al. 2004).

Lattice-based models have some advantages compared to the traditional numerical methods (Rothman and Zaleski 1994). The simulation occurs in a regular lattice and can be efficiently implemented in a massively parallel computer. Solid boundaries and multiple fluids can be introduced in a simple way, and the simulation is done efficiently, regardless of the complexity of boundary or the interface (Buick et al. 1998). In the case of lattice gas cellular automata (LGCA), there are no numerical stability problems because their evolution follows integer arithmetic. For LBM, accuracy and numerical stability depend on the Mach number, which is the ratio of maximum speed to the speed of sound. The computational cost of the LGCAs is lower than the cost of LBM methods.

© Springer Nature Switzerland AG 2024
N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

However, the system parameterization (e.g., viscosity) is difficult to do in LGCA models, and the dynamics obtained is less realistic than for the LBM.

This article will demonstrate how to use the advantages of lattice Boltzmann method to solve diffusion-reaction problems.

Theoretical Foundations

Diffusion is an example of a matter transport phenomenon where the particles of a set move randomly and spread in the medium containing them. For example, we can smell perfume because it diffuses into the air and makes its way into our nose. From macroscopic point of view, these movements cause the set to move from the higher-concentration zones to the low-concentration zones. Diffusion-reaction equations arise naturally in systems consisting of many interacting components, like chemical reactions, and are widely used to describe pattern formation phenomena in a variety of biological, chemical, and physical systems.

The diffusion equation is given by

$$\frac{\partial \phi}{\partial t} = \alpha \frac{\partial^2 \phi}{\partial \mathbf{x}^2} + F, \tag{1}$$

where $\alpha(\mathbf{x}) > 0$ is the diffusion coefficient in $\mathbf{x}$, $\boldsymbol{\phi}(\mathbf{x},t)$ is the amount that is being diffused, and $F(\phi,\mathbf{x},t)$ is a portion of internal contribution (source term). The portion on the left is time variation, and the first portion on the right is spatial variation.

Finite Difference Approximation

The following analysis was performed by Mohamad (Mohamad 2011), for a one-dimensional problem; however, the extension for two-dimensional and three-dimensional problems is analogous. Moreover, the analysis takes into account diffusion Eq. (1) without the source term. A finite difference method will be used in the temporal term, and central differences in the spatial term, giving us the following approximation of the diffusion equation in a given node i:

$$\frac{T_i^{n+1} - T_i^n}{\Delta t} = \alpha \frac{T_{i+1}^n - 2T_i^n + T_{i-1}^n}{\Delta x^2}, \tag{2}$$

where T_i^n corresponds to the amount that is being diffused at node i at time step n, Δt is the discrete time step, and Δx is the discrete spatial step.

Isolating the term of interest from Eq. (2), we have

$$T_i^{n+1} = T_i^n + \frac{\alpha \Delta t}{\Delta x^2}\left(T_{i+1}^n - 2T_i^n + T_{i-1}^n\right). \tag{3}$$

Equation (3) can be rearranged as follows:

$$T_i^{n+1} = T_i^n\left(1 - \frac{2\alpha\Delta t}{\Delta x^2}\right) + \frac{2\alpha\Delta t}{\Delta x^2} \times \left(\frac{T_{i+1}^n + T_{i-1}^n}{2}\right). \tag{4}$$

Defining

$$\tau = \frac{2\alpha \Delta t}{\Delta x^2},$$

we have then

$$T_i^{n+1} = T_i^n(1-\tau) + \tau\left(0.5T_{i+1}^n + 0.5T_{i-1}^n\right). \tag{5}$$

The finite difference approximation steps were performed in a way that could be compared to the LBM methodology. Following the considerations of Mohamad (2011), the last term in Eq. (5) is an average of the quantity around T_i or, in other words, represents an equilibrium term of T_i. In this way, Eq. (5) can be rewritten as follows:

$$T_i^{n+1} = T_i^n(1-\tau) + \tau T_i^{eq}, \tag{6}$$

where T_i^{eq} is the equilibrium term of T_i.

Formulation of the LBM for Diffusion

The LBM is a numerical method whose equations are formulated on a mesoscopic scale. This

method is able to simulate the dynamics of fluids on a macroscopic scale (Chen and Doolen 1998). In the LBM, the fluid is represented by a set of particles which reside in a regular lattice with certain properties of symmetry. The dynamics that governs the simulation involves steps of collision and scattering of these particles through the lattice directions, following simple rules that satisfy the laws of conservation of mass (number of particles) and momentum. The macroscopic behavior of the fluid is obtained through statistical results on the data at the microscale. This section shows the formulation of the LBM for solving diffusion problems.

The kinetic equation for the distribution function $f_i(\mathbf{x},t)$ can be written as follows (Mohamad 2011):

$$\frac{\partial f_i(\mathbf{x},t)}{\partial t} + c_i \frac{\partial f_i(\mathbf{x},t)}{\partial \mathbf{x}} = \Omega_i \tag{7}$$

where i varies among the possibilities of direction for each cell, depending on the dimension of the problem. Among the available models, those that represent the Navier-Stokes equations are called $DnQb$ (where n refers to the dimension and b the number of lattice directions), proposed by Quian et al. (1992). For example, a 1D problem has one dimension and two lattice directions, so the model is called $D1Q2$. However, for 2D problems, the most common model used is $D2Q9$, which takes into account the diagonal directions.

The term on the left in Eq. (7) represents the scattering process, where the distribution functions evolve along the lattice directions with velocity $c_i = \Delta x/\Delta t$. The term on the right represents the rate of change of the distribution function in the collision process. According to Chopard et al. (2002), the most natural way to define the collision term is by averaging the micro-dynamics and factoring it into a product of average quantities. However, for more sophisticated fluids, the collision term requires a large number of floating point operations at each node of the lattice at each instant of time, which would increase the computational cost. One solution is to use the BGK approximation, which uses a relaxation term toward the local equilibrium (Bhatnagar et al. 1954).

The collision operator can be represented by the BGK approximation:

$$\Omega_i = -\frac{1}{\omega}\left[f_i(\mathbf{x},t) - f_i^{eq}(\mathbf{x},t)\right], \tag{8}$$

where ω represents a temporal relaxation on the equilibrium distribution function, related to the diffusion coefficient on the macroscopic scale.

Equation (7) with the BGK approximation can be discretized as follows:

$$\begin{aligned}&\frac{f_i(\mathbf{x},t+\Delta t) - f_i(\mathbf{x},t)}{\Delta t} \\ &\quad + c_i \frac{f_i(\mathbf{x}+\Delta x, t+\Delta t) - f_i(\mathbf{x},t+\Delta t)}{\Delta x} \\ &\quad = -\frac{1}{\omega}\left[f_i(\mathbf{x},t) - f_i^{eq}(\mathbf{x},t)\right].\end{aligned} \tag{9}$$

Replacing $\Delta x = c_i \Delta t$, we simplify to

$$\begin{aligned}&f_i(x+\Delta x, t+\Delta t) - f_i(\mathbf{x},t) \\ &\quad = -\frac{\Delta t}{\omega}\left[f_i(\mathbf{x},t) - f_i^{eq}(\mathbf{x},t)\right].\end{aligned} \tag{10}$$

What leads us to

$$\begin{aligned}f_i(\mathbf{x}+\Delta x, t+\Delta t) = f_i(\mathbf{x},t)[1-\tau] \\ + \tau f_i^{eq}(\mathbf{x},t),\end{aligned} \tag{11}$$

where $\tau = \Delta t/\omega$ is called temporal relaxation.

The dependent variable ϕ in reaction-diffusion Eq. (1) is related to the distribution function as follows (for $D2Q9$ model):

$$\phi(\mathbf{x},t) = \sum_{i=0}^{8} f_i(\mathbf{x},t). \tag{12}$$

The relationship between the diffusion coefficient α and the temporal relaxation term τ can be deduced by a multi-scale expansion (Mohamad 2011), providing

$$\alpha = \frac{\Delta x^2}{\Delta t D}\left(\frac{1}{\tau} - \frac{1}{2}\right), \tag{13}$$

L

where D corresponds to the dimension of the problem.

For diffusion problems, assume constant the equilibrium distribution functions, not having macroscopic velocity action:

$$f_i^{eq} = A_i. \tag{14}$$

The equilibrium distribution function must satisfy mass conservation and momentum:

$$\sum_{i=0}^{8} f_i^{eq} = \Theta \tag{15}$$

and

$$\sum_{i=0}^{8} f_i^{eq} c_i = 0. \tag{16}$$

In general, $A_i = w_i\Theta$, which implies $f_i^{eq} = w_i\Theta$. The equilibrium distribution function for the diffusion problem can be chosen as follows (Mohamad 2011):

$$f_i^{eq} = w_i\phi(\mathbf{x}, t), \tag{17}$$

with ϕ given by Eq. (12) and w_i are weight factors relative to each direction of movement. The factors w_i shall meet the following criteria:

$$\sum_{i=0}^{8} w_i = 1. \tag{18}$$

In this way, the equilibrium distribution functions can be summed in all directions, providing

$$\sum_{i=0}^{8} f_i^{eq}(\mathbf{x}, t) = \sum_{i=0}^{8} w_i\phi(\mathbf{x}, t) = \phi(\mathbf{x}, t). \tag{19}$$

LBM Diffusion-Reaction to Vector Field

So far we have shown the general formulation of the LBM for diffusion problems. In this section, we will apply this formulation to the problem of diffusion-reaction in vector fields. The reaction term can be treated as a source term in the LBM formulation. Thus, the LBM formula for reaction-diffusion problems is given by (Mohamad 2011)

$$\begin{aligned}\mathbf{f}_i(\mathbf{x} + \Delta\mathbf{x}, t + \Delta t) = {} & \mathbf{f}_i(\mathbf{x}, t)[1 - \tau] \\ & + \tau\mathbf{f}_i^{eq}(\mathbf{x}, t) \\ & + \Delta t w_i \mathbf{R},\end{aligned} \tag{20}$$

where $\mathbf{R}$ is the reaction term. In the formulation, $\mathbf{f}_i$ corresponds to the quantity being diffused. In this case, we want to apply the diffusion in a two-dimensional vector field: $\mathbf{f}_i(\mathbf{x}, t) = \left(f_i^u(\mathbf{x}, t), f_i^v(\mathbf{x}, t)\right)$.

In practical terms, this implies a duplicate structure, that is, we will now have a lattice for the component x and a lattice for the component y, and apply the LBM separately as follows:

$$\begin{aligned}f_i^u(\mathbf{x} + \Delta\mathbf{x}, t + \Delta t) = {} & f_i^u(\mathbf{x}, t)[1 - \tau] \\ & + \tau f_i^{u,eq}(\mathbf{x}, t) \\ & + \Delta t w_i R_u,\end{aligned} \tag{21}$$

$$\begin{aligned}f_i^v(\mathbf{x} + \Delta\mathbf{x}, t + \Delta t) = {} & f_i^v(\mathbf{x}, t)[1 - \tau] \\ & + \tau f_i^{v,eq}(\mathbf{x}, t) \\ & + \Delta t w_i R_v.\end{aligned} \tag{22}$$

The reaction term will be treated as the source term in the LBM (Mohamad 2011). In this way, the dynamics in (20) is rewritten as follows:

$$\begin{aligned}\mathbf{f}_i(\mathbf{x} + \Delta\mathbf{x}, t + \Delta t) = {} & \mathbf{f}_i(\mathbf{x}, t)[1 - \tau] \\ & + \tau\mathbf{f}_i^{eq}(\mathbf{x}, t) + \Delta t R_i,\end{aligned} \tag{23}$$

where:

$$R_i = \frac{w_i \mathbf{R} \cdot \mathbf{c}_i}{c_s^2}, \tag{24}$$

where $c_s = 1/\sqrt{3}$ is called speed of sound and w_i are weighting factors related to each of the i's directions.

The temporal relaxation parameter τ is related to the diffusion coefficient through Eq. (13). Finally, the equilibrium distribution will then be given by

$$f_i^{u,eq} = w_i u(\mathbf{x}, t), \tag{25}$$

$$f_i^{v,eq} = w_i v(\mathbf{x}, t), \tag{26}$$

where:

$$u(\mathbf{x}, t) = \sum_{i=0}^{8} f_i^u(\mathbf{x}, t), \tag{27}$$

$$v(\mathbf{x}, t) = \sum_{i=0}^{8} f_i^v(\mathbf{x}, t). \tag{28}$$

Definitions

- **Cellular Automata**
  A mathematical model based on simple and local rules capable of generating complex behaviors.
- **LBM**
  Lattice Boltzmann method, a numerical method based in kinetic equations formulated on a mesoscopic scale.
- **LGCA**
  Lattice gas cellular automata, a specific cellular automaton, whose proposal is to simulate fluids using simple and local rules that imitate a particle dynamics.

Introduction

The lattice Boltzmann method is a numerical method based in kinetic equations formulated on a mesoscopic scale, which simulates fluid dynamics on a macroscopic scale (Chen and Doolen 1998). In the last years, LBM has drawn the attention of the scientific community due to its ease of implementation and computational efficiency. Specifically in fluid dynamics, LBM has been used due to its ease of boundary conditions implementations (Chopard et al. 2002).

The method originated from the lattice gas cellular automata (LGCA) that, despite its advantages, is limited by its discrete nature: the

appearance of artifacts in the characteristic directions of the lattice and little flexibility to adjust physical parameters and initial conditions (Adilson Vicente Xavier 2006; Chen and Doolen 1998). It was later demonstrated that the dynamics of the LBM can be derived through the Boltzmann equation (He and Luo 1997a; Philippi et al. 2006).

Cellular automata is a mathematical model based on simple and local rules capable of generating complex behaviors. It was originally introduced by John von Neumann, under the name of cellular spaces, as an idealization of biological systems, with the particular goal to model systems capable of self-reproduction (Wolfram 1994). The LGCA is a specific cellular automaton, whose proposal is to simulate fluids using simple and local rules that imitate a particle dynamics. The essential characteristics of the microscopic interactions that are taken into account are the laws of conservation of linear momentum and conservation of the number of particles (Chopard and Droz 1998).

The LBM was introduced by McNamara and Zanetti (1988), where the authors show the advantage of extending the Boolean dynamic of cellular automaton to work directly with floating point numbers representing probabilities of particle presence.

Theoretical Foundations

The LGCAs are cellular automata that simulate fluids through simple models. In the LGCA, the fluid is represented by a set of particles which reside in a regular lattice with certain properties of symmetry. The dynamics that governs the simulation involves steps of collision and scattering of these particles through the lattice directions, following simple rules that satisfy the laws of conservation of mass (number of particles) and momentum. The macroscopic behavior of the fluid is obtained through statistical results on the data at the microscale.

The dynamics of microparticles in the LGCA model is described by the equation given below (Daniel Reis Golbert 2009):

$$n_i(\mathbf{x} + \mathbf{c}_i, t + \delta r) = n_i(\mathbf{x}, t) + \Delta_i(n(\mathbf{x}, t)), \quad (1)$$

where $n_i(\mathbf{x}, t)$ can assume the values 0 or 1 representing the absence or presence of particle moving from the cell in the position $\mathbf{x}$ to the neighboring cell $\mathbf{x} + \mathbf{c}_i$ at time step t ($\mathbf{c}_i$ are the directions of movement). The function Δ_i is a collision operator representing the influence of particle collisions. The index i represents the z possible directions of movement of the lattice, that is, $i = 1, \ldots z$.

Conditions of mass conservation and moment conservation are imposed on the collision operator, respectively, given by:

$$\sum_i \Delta_i(\mathbf{n}) = 0 \quad \text{and} \quad \sum_i \mathbf{c}_i \Delta_i(\mathbf{n}) = 0. \quad (2)$$

The physical quantities of interest are the macroscopic quantities, such as the specific mass and linear momentum at a point in the system (Chopard and Droz 1998). The distribution which corresponds to the probability of having a particle in the node $\mathbf{x}$, at time step t is defined as (Chopard et al. 2002):

$$N_i(\mathbf{x}, t) = \langle n_i(\mathbf{x}, t) \rangle, \quad i = 1, \ldots, z. \quad (3)$$

Following the usual definition of statistical mechanics (Chopard and Droz 1998), the local density of particles is the sum of the probabilities of the microscopic variables of occupation (Expression 3):

$$\rho(\mathbf{x}, t) = \sum_{i=1}^{z} N_i(\mathbf{x}, t). \quad (4)$$

Similarly, the linear momentum ($\rho\mathbf{u}$) is given by Chopard and Droz (1998):

$$\rho(\mathbf{x}, t)\mathbf{u}(\mathbf{x}, t) = \sum_{i=1}^{z} \mathbf{v}_i N_i(\mathbf{x}, t), \quad (5)$$

where $\mathbf{v}_i$ are the speeds related to each direction of movement. The time step is defined as δ_t and the displacement between the nodes of the lattice as δ_x. Thus, the six possible velocities $\mathbf{v}_i$ of the

particles are related to their directions of motion by:

$$\mathbf{v}_i = \frac{\delta_x}{\delta_t}\mathbf{c}_i. \quad (6)$$

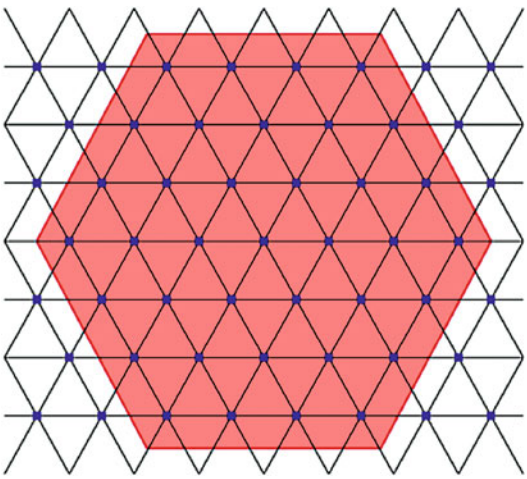
From LGCA to LBM Dynamics

The dynamics of the LGCA method are related to quantities present on the microscale. In the case of LBM, this dynamics occurs in the mesoscale (particle distributions), where the individual movements of each particle are not visible. In the mesoscale we will work with averages taken on regions of the lattice, so that these averages vary smoothly in both space and time (Guo and Shu 2013). Thus, we will use the (3) distribution covering an area of the lattice, rather than just a node. The N_i value will represent mean values of the distribution of microparticles described by the Boolean variables n_i over a region of the lattice, as shown in Fig. 1 (Daniel Reis Golbert 2009).

Applying the calculation of the averages on the LGCA equation of motion (1) we will arrive at the equation:

$$N_i(\mathbf{x} + \mathbf{c}_i\Delta x, t + \Delta t) = N_i(\mathbf{x}, t) + \langle \Delta_i(\mathbf{n}) \rangle, \quad (7)$$

where Δx represents the new spacing and Δt the new step of time considered in the mesoscale.



Lattice Boltzmann Method for Fluid Simulation, Fig. 1 Representation of a region of the hexagonal lattice

The collision term can be simplified by considering that the particles motion is not correlated before the collision step (principle of molecular chaos). Thus, the collision operator can be applied directly to the quantity representing the mean of the distribution of microparticles in the region of the lattice:

$$N_i(\mathbf{x} + \mathbf{c}_i\Delta x, t + \Delta t) - N_i(\mathbf{x}, t) = \Delta_i(\mathbf{N}). \quad (8)$$

Thus, we arrive at an equation similar to the lattice Boltzmann equation in the mesoscale, defined as (Daniel Reis Golbert 2009):

$$f_i(\mathbf{x} + \mathbf{c}_i\Delta x, t + \Delta t) - f_i(\mathbf{x}, t) = \Omega_i(\mathbf{f}(\mathbf{x}, t)), \quad i = 1, \ldots, z, \quad (9)$$

where f_i is called the particle distribution function (which assumes floating point values) and Ω_i the collision operator.

The macroscopic quantities of interest are calculated analogously to the process given in the LGCA (Eqs. (4) and (5)), where the density of particles is given by:

$$\rho(\mathbf{x}, t) = \sum_{i=1}^{z} f_i(\mathbf{x}, t), \quad (10)$$

and the linear momentum ($\rho\mathbf{u}$) is given by:

$$\rho(\mathbf{x}, t)\mathbf{u}(\mathbf{x}, t) = \sum_{i=1}^{z} \mathbf{c}_i f_i(\mathbf{x}, t). \quad (11)$$

BGK Approximation

The LBM is a numerical method whose equations are formulated on a mesoscopic scale, although it is able to simulate the dynamics of fluids on a macroscopic scale (Chen and Doolen 1998). The dynamics of this method is governed by the lattice Boltzmann Eq. (9).

According to (Chopard et al. 2002), the most natural way to define the collision term is by averaging the micro-dynamics and factoring it into a product of average quantities. However, for more sophisticated fluids, the collision term requires a large number of floating point

operations at each node of the lattice at each instant of time, which would increase the computational cost. One solution is to use the BGK approximation.

The BGK approach for the collision operator uses a relaxation term toward the local equilibrium (Bhatnagar et al. 1954). Thus, the collision operator through the BGK approximation is given by:

$$\Omega_i(\mathbf{f}(\mathbf{x},t)) = -\frac{1}{\tau}\left(f_i(\mathbf{x},t) - f_i^{\mathrm{eq}}(\mathbf{x},t)\right), \quad (12)$$

where τ is the relaxation term, which is related to the diffusive phenomena in the problem (viscosity of the fluid), and f_i^{eq} is the local equilibrium distribution function, which can be given by Eq. (14) forward. Thus, the lattice Boltzmann equation with BGK approximation is given by:

$$f_i(\mathbf{x}+\mathbf{c}_i\Delta x, t+\Delta t) - f_i(\mathbf{x},t) = -\frac{1}{\tau}\left(f_i(\mathbf{x},t) - f_i^{\mathrm{eq}}(\mathbf{x},t)\right). \quad (13)$$

In this model called lattice BGK (LBGK), the local equilibrium distribution was chosen so that the Navier-Stokes equations can be recovered asymptotically (Chen and Doolen 1998). The general form of this equilibrium distribution is given by Chopard and Droz (1998), Guo and Shu (2013):

$$f_i^{\mathrm{eq}}(\mathbf{x},t) = \rho\omega_i\left[A + B\frac{(\mathbf{c}_i\cdot\mathbf{u})}{c_s^2} + C\frac{(\mathbf{c}_i\cdot\mathbf{u})^2}{2c_s^4} + D\frac{(\mathbf{u}\cdot\mathbf{u})}{2c_s^2}\right], \quad (14)$$

where ω_i are weight factors related to the directions of the lattice, $\boldsymbol{\rho}$ and $\mathbf{u}$ are the macroscopic quantities of particle density and velocity (given, respectively, by Eqs. (10) and (11)), c_s is called the sound velocity, and A, B, C, and D are constant, whose values depend on the model used. These constants of the equilibrium distribution are related to the symmetry imposed on the mesh models used, which are necessary to recover the Navier-Stokes Equations (Daniel Reis Golbert 2009).

The LBGK models are the most used among the LBM models for fluid simulation. Among the available models, those that represent the Navier-Stokes equations are called *DnQb* (where *n* refers to the dimension and *b* the number of lattice directions), proposed by Quian et al. (1992), whose parameter values are shown in Table 1.

Incompressible Equilibrium Distribution Function

Applying a Chapman-Enskog multiscale asymptotic expansion in the lattice Boltzmann equation and assuming that the velocity of the fluid is less than the velocity of sound, it can be shown that it is possible to derive the incompressible Navier-Stokes Equations (Chopard et al. 2002). Therefore, it is necessary to use an incompressible equilibrium distribution function, which reduces the inherent compressibility effects of the LBM.

Lattice Boltzmann Method for Fluid Simulation, Table 1 Parameters of some models *DnQb*

Model	Direction vector $\mathbf{c}_i$	Weights ω_i	c_s^2
D1Q3	0, ±1	2/3, 1/6	1/3
D1Q5	0, ±1, ±2	6/12, 2/12, 1/12	1
D2Q7	(0,0), (±l/2,±$\sqrt{3}$/2)	1/2, 1/12	1/4
D2Q9	(0,0), (±1,0),(0,±1), (±1,±1)	4/9, 1/9, 1/36	1/3
D3Q15	(0,0,0), (±1,0,0),(0,±1,0), (0,0,±1), (±1,±1,±1)	2/9, 1/9, 1/72	1/3
D3Q19	(0,0,0), (±1,0,0),(0,±1,0), (0,0,±1), (±1,±1,0),(±1,0,±1), (0,±1,±1)	1/3, 1/18, 1/36	1/3

In an incompressible fluid, the density is approximately constant (denoted by ρ_0) and its fluctuation (denoted by $\delta\rho$) must be of the order $O(M^2)(M \to 0)$, where $M = \mid \mathbf{u} \mid /c_s$ is the Mach number. Thus, and seeking to reduce the compressibility errors that arise when using the equilibrium distribution function (14), the authors in He and Luo (1997b) proposed a modified version of it:

$$f_i^{\text{eq}} = w_i\left\{\rho + \rho_0\left[3(\mathbf{c}_i \cdot \mathbf{u}) + \frac{9}{2}(\mathbf{c}_i \cdot \mathbf{u})^2 - \frac{3}{2}(\mathbf{u} \cdot \mathbf{u})\right]\right\}. \quad (15)$$

With the use of this equilibrium distribution, the incompressible Navier-Stokes equations are recovered, with approximation orders in terms of the Mach number (Daniel Reis Golbert 2009):

$$\nabla \cdot \mathbf{u} = 0 + O(M^2), \quad \text{e} \quad (16)$$

$$\frac{\partial \mathbf{u}}{\partial r} + \mathbf{u} \cdot \nabla \mathbf{u} = -\nabla P + \overline{\nu}\nabla^2 \mathbf{u} + O(M^3), \quad (17)$$

where $P = c_s^2 \rho/\rho_0$ is the normalized pressure and $\overline{\nu}$ is the kinematic viscosity of the fluid, described by:

$$\overline{\nu} = \frac{2\tau - 1}{6}\frac{\Delta x^2}{\Delta t}. \quad (18)$$

It is noted that a value equal to 0.5 for the parameter τ implies in viscosity of the fluid identically null, situation not contemplated in the model. Values less than 0.5 indicate negative viscosities, which would be in disagreement with the laws of thermodynamics. From Eq. (18), we have:

$$\tau = 3\overline{\nu}\frac{\Delta t}{\Delta x^2} + \frac{1}{2}. \quad (19)$$

According to (Daniel Reis Golbert 2009), not found in the literature, a minimum value for the parameter τ guarantees the numerical stability of the method. Numerical instabilities appear when τ is close to 0.5.

D2Q9 Model

The lattice Boltzmann model known as D2Q9 has eight nonzero motion directions and the possibility of having a resting particle. It is a two-dimensional model, as illustrated in Fig. 2.

In the D2Q9 model, the time step is discrete, and for each lattice node, there are nine possible directions of motion, where $\mathbf{c}_0$ represents the lattice node itself, whose velocity is zero (Chen and Doolen 1998; Chopard et al. 2002). In this way, the number of possible directions is given by $z = 0, \ldots, 8$.

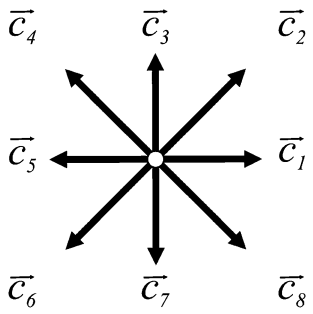
The eight possible velocities $\mathbf{v}_i$, given by Expression (6), are related to directions of movement $\mathbf{c}_i$ (Fig. 2), described by:

$$\begin{array}{lll} \mathbf{c}_0 = (0,0), & \mathbf{c}_1 = (1,0)v, & \mathbf{c}_2 = (1,1)v, \\ \mathbf{c}_3 = (0,1)v, & \mathbf{c}_4 = (-1,1)v, & \mathbf{c}_5 = (-1,0)v, \\ \mathbf{c}_6 = (-1,-1)v, & \mathbf{c}_7 = (0,-1)v, & \mathbf{c}_8 = (1,-1)v \end{array} \quad (20)$$

Two velocities are introduced, according to the distance to be traveled in a time step, namely:

- The slow velocities with module given by $v = \Delta_x/\Delta_t$ in the vertical and horizontal directions ($\mathbf{c}_1$, $\mathbf{c}_3$, $\mathbf{c}_5$, $\mathbf{c}_7$)
- Fast velocities with module $\sqrt{2}v$ in the diagonal directions ($\mathbf{c}_2$, $\mathbf{c}_4$, $\mathbf{c}_6$, $\mathbf{c}_8$)

This occurs due to the different distances that distributions must travel, in the same time interval, to reach the neighboring nodes.



Lattice Boltzmann Method for Fluid Simulation, Fig. 2 Direction of motion in the lattice of D2Q9

The update rule for the D2Q9 model follows the BGK model described in the Eq. (13). However, it is common to divide the dynamics of the LBM into two steps, namely: collision and scattering. Figure 3 illustrates the complete dynamics procedure divided into these steps.

The collision step is governed by the following equation:

$$f_i(\mathbf{x}, t + \Delta t) = f_i(\mathbf{x}, t)[1 - \tau] + \tau f_i^{\text{eq}}(\mathbf{x}, t). \quad (21)$$

The scattering step is governed by another equation given below:

$$f_i(\mathbf{x} + \Delta\mathbf{x}, t + \Delta t) = f_i(\mathbf{x}, t + \Delta t). \quad (22)$$

The general form of the equilibrium distribution function is described by Eq. (14). The author in (He and Luo 1997a) obtains the following values of weights ω_i and constants for the model D2Q9 (see Table 1):

$$f_i^{\text{eq}} = \rho\omega_i\left[1 + 3(\mathbf{c}_i \cdot \mathbf{u}) + \frac{9}{2}(\mathbf{c}_i \cdot \mathbf{u})^2 - \frac{3}{2}\mathbf{u}^2\right], \quad (23)$$

where:

$$\omega_0 = \frac{4}{9}, \quad \omega_i = \frac{1}{9}, \quad (i = 1, 3, 5, 7), \quad \omega_i = \frac{1}{36}, (i = 2, 4, 6, 8).$$

The macroscopic amounts of density (ρ) and velocity ($\mathbf{u}$) are given, respectively, by:

$$\rho(\mathbf{x}, t) = \sum_{i=0}^{8} f_i(\mathbf{x}, t), \quad (24)$$

$$\mathbf{u}(\mathbf{x}, t) = \frac{1}{\rho(\mathbf{x}, t)} \sum_{i=1}^{8} f_i(\mathbf{x}, t)\mathbf{c}_i. \quad (25)$$

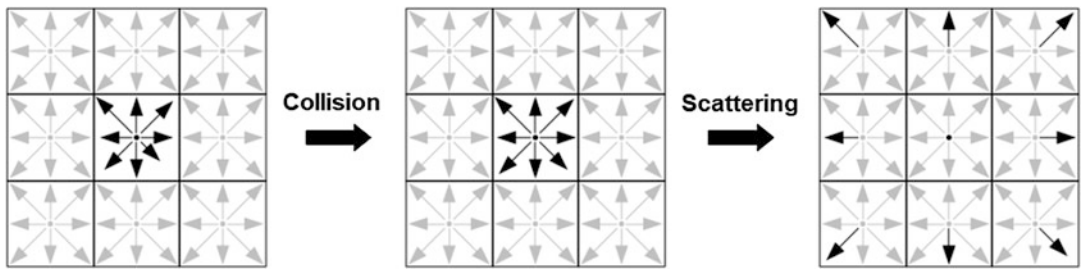
Boundary Conditions

Different types of contour conditions have been introduced in the field of hydrodynamics for the LBM. Bounce back is the simplest of them (Rothman and Zaleski 1997), used in boundary conditions whose walls are not slippery, that is, the nodes present in the walls present zero velocity in all directions. When the particles propagate to a boundary node, they simply return in the same direction they were.

Because of its simplicity, such a method cannot adequately represent curved boundary problems without introducing noise into the solution, especially in poorly refined lattices. An incorrect value may eventually cause a negative density value, generating an error that may accumulate along the evolution (Rothman and Zaleski 1997).

The periodic boundary condition is a simple option to apply. Basically, it is necessary to connect the ends of the domain according to the desired directions. Figure 4 shows the topologies of the domains when applying periodic boundary conditions in one direction and two directions in a two-dimensional model.

Another boundary condition is proposed by Zou and He (1997), where the authors impose velocity values (not necessarily null) on the



Lattice Boltzmann Method for Fluid Simulation, Fig. 3 Steps of LBM dynamics

centers of the border nodes. The basic idea is to introduce a step, between the collision step (21) and propagation step (22), to calculate the distributions in some directions of the boundary nodes.

After the propagation, the f_is from the interior and from the border itself are known at the border nodes. The unknown f_is as well as the density (ρ) of the boundary node are calculated from the mass conservation Eq. (24), of the linear momentum conservation Eq. (25), where boundary velocity is imposed, and through the reflection of the so-called non-equilibrium part (Zou and He 1997):

$$f_i - f_i^{\text{eq}} = f_{i+z/2} - f_{i+z/2}^{\text{eq}}, \tag{26}$$

where z represents the number of nonzero directions of the lattice. The D2Q9 model has $z = 8$.

To exemplify the abovementioned boundary condition, we show two-boundary situations in the D2Q9 model: boundary nodes present on the walls (Fig. 5a) and frontier nodes present in the corners of lattice (Fig. 5b).

The first situation shows the case of a border node present in the bottom wall. After the propagation (22), the distributions f_1, f_5, f_6, f_7, and f_8 are known, because they come from the neighboring nodes. According to the boundary condition proposed by Zou and He (1997), we will impose a velocity value (**u**) on the border nodes present on the bottom wall. To determine the four unknown variables (f_2, f_3, f_4, and ρ), we will use the mass conservation Eq. (24):

$$f_2 + f_3 + f_4 = \rho - (f_0 + f_1 + f_5 + f_6 + f_7 + f_8), \tag{27}$$

the conservation equations of linear momentum (25) in x direction:

$$f_2 - f_4 = \rho u_x - f_1 + f_5 + f_6 - f_8, \tag{28}$$

Lattice Boltzmann Method for Fluid Simulation, Fig. 5 Boundary of D2Q9 model. (**a**) An example of a node present on the bottom wall. (**b**) An example of a node in the corner of the lattice

and y direction:

$$f_2 + f_3 + f_4 = \rho u_y + f_6 + f_7 + f_8. \quad (29)$$

From Eqs. (27) and (29), we have:

$$\rho = \frac{1}{1 - u_y} \times [f_0 + f_1 + f_5 + 2(f_6 + f_7 + f_8)]. \quad (30)$$

However, f_2, f_3, and f_4 remain indeterminate. In this way, we use the reflection of the non-equilibrium part of the distribution f_7:

$$f_3 - f_3^{eq} = f_7 - f_7^{eq}. \quad (31)$$

From Eqs. (27, 28, 29, 30, and 31) we can calculate the unknown variables:

$$f_3 = f_7 + \frac{2}{3}\rho u_y \quad (32)$$

$$f_4 = f_8 + \frac{1}{2}(f_1 - f_5) - \frac{1}{2}\rho u_x + \frac{1}{6}\rho u_y \quad (33)$$

$$f_2 = f_6 - \frac{1}{2}(f_1 - f_5) + \frac{1}{2}\rho u_x + \frac{1}{6}\rho u_y. \quad (34)$$

An analogous procedure is applied to the nodes that are present in the corners of the lattice. As an example, let's look at the node in the lower-right corner, as shown in Fig. 5b. After propagation (22), the distributions f_0, f_1, f_7, and f_8 are known. We will impose them a velocity value ($\mathbf{u}$), and to determine the six unknown variables (f_2, f_3, f_4, f_5, f_6, and ρ), we will use the mass conservation Eq. (24):

$$f_2 + f_3 + f_4 + f_5 + f_6 = \rho - (f_0 + f_1 + f_7 + f_8), \quad (35)$$

the conservation equations of linear momentum (25) in x direction:

$$f_2 - f_4 - f_5 - f_6 = \rho u_x - (f_1 + f_8), \quad (36)$$

and y direction:

$$f_2 + f_3 + f_4 - f_6 = \rho u_y + f_7 + f_8. \quad (37)$$

With three equations and six unknown variables, it is not possible to determine ρ. In this way, the density at the border node in the lower-right corner will be determined by the average of the neighboring densities. However, f_2, f_3, f_4, f_5, and f_6 remain indeterminate. We then use the reflection of the non-equilibrium part of the distribution f_1 and f_7:

$$f_5 - f_5^{eq} = f_1 - f_1^{eq}. \quad (38)$$

$$f_3 - f_3^{eq} = f_7 - f_7^{eq} \quad (39)$$

From Eqs. (35, 36, 37, 38, and 39) and the estimated density value (ρ), we are able to calculate the unknown variables:

$$f_3 = f_7 + \frac{2}{3}\rho u_y \quad (40)$$

$$f_5 = f_1 - \frac{2}{3}\rho u_x \quad (41)$$

$$f_4 = f_8 - \frac{1}{6}\rho u_x + \frac{1}{6}\rho u_y \quad (42)$$

$$f_6 = \frac{1}{2}(\rho - f_0) - (f_1 + f_7 + f_8) + \frac{1}{3}\rho u_x - \frac{1}{2}\upsilon u_y \quad (43)$$

$$f_2 = \frac{1}{2}(\rho - f_0) - (f_1 + f_7 + f_8) + \frac{1}{2}\rho u_x - \frac{1}{3}\rho u_y. \quad (44)$$

Algorithm 1 shows all the steps of the LBM methodology for the D2Q9 model.

Definitions

- **Cellular automata**
  Mathematical models based on simple and local rules capable of generating complex behaviors.
- **Computational fluid dynamics (CFD)**
  Area of knowledge that studies computational methods to solve problems in fluid dynamics.
- **FHP**
  A specific cellular automata model to simulate fluid dynamics.
- **Lattice gas cellular automata (LGCA)**
  Cellular automata that simulates specifically fluid problems.

Introduction

In recent decades, techniques based on physical models for the animation of natural elements, such as fluids (gas or liquid), have drawn the attention of the researchers in computer graphics. The motivation lies in the potential in the applications of these techniques as well as in the complexity and beauty of the natural phenomena involved. In particular, techniques in the field of computational fluid dynamics (CFD) have been implemented for fluid animation.

Numerical methods in DFC for fluid simulation, such as finite differences and finite elements (Hughes 1987), try to describe a continuous system through the discretization of the equations that represent it. However, such methods have a high computational cost. Another alternative in this area is the use of techniques based on cellular automata (Wolfram 1994; Sarkar 2000; Kari 2005). Such methods seek to obtain the macroscopic dynamics of the fluid through the collective behavior of numerous microscopic particles. The specific cellular automata to simulate fluids are called lattice gas cellular automata (LGCA) and follow this idea by simplifying the dynamics through simple local rules for the interactions and displacement of the microscopic particles.

While traditional CFD modeling attempts to represent a continuous medium starting from macroscopic variables and partial differential equations (PDE), the LGCA modeling follows the inverse path, that is, from the microscopic description based on simple rules, it tries to obtain the macroscopic behavior (bottom up) without, however, explicitly solving any system of PDE (Chopard and Droz 1998). The macroscopic behavior is obtained through computational simulation, based on the set of rules governing the system, and simple interpolations.

LGCA can be seen as a simplified universe. Space is represented by a uniform lattice, where each cell contains Boolean data, the time step is discrete, and the laws governing that universe are expressed by simple rules of local collisions. They are discrete models, based on particles whose movement is restricted to the directions of the lattice edges. These methods have a lower computational cost and are more stable compared to the traditional ones used in fluid simulation, due to the fact that it is not necessary to calculate PDE to obtain the desired level of physical realism (Rothman and Zaleski 1997).

Among the varieties of automata of the LGCA type, this article will talk about the FHP model for its simplicity and computational efficiency (Chopard and Droz 1998). FHP was developed to simulate two-dimensional fluids. The space is discretized in a hexagonal lattice, that is, in each lattice node, there are six possible directions of movement. In addition, a multiscale technique was applied in order to demonstrate that the FHP model is capable of reproducing Navier-Stokes behaviors for two-dimensional fluids (Frisch et al. 1986).

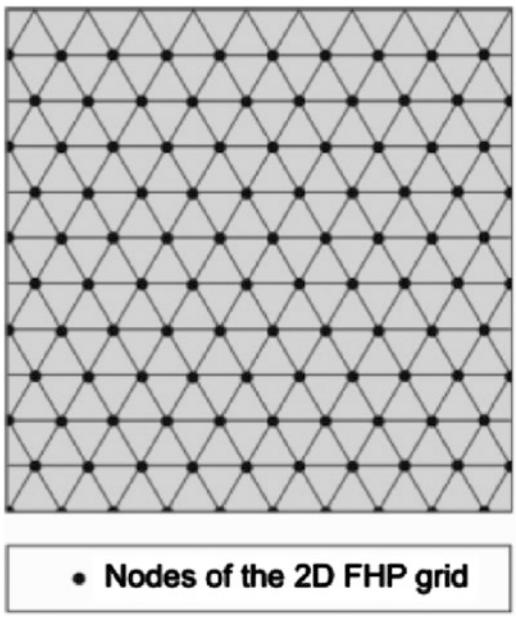
FHP Model

The FHP model was introduced by Frisch, Hasslacher, and Pomeau (Frisch et al. 1986), where FHP represents the name initials of their authors. It is a specific cellular automaton for fluid simulation, known as lattice gas cellular automata. Although the LGCAs cannot compete with traditional techniques of computational fluid dynamics, particularly for high Reynolds numbers, several authors have succeeded in using such

models to simulate complex systems, for which traditional techniques are difficult to apply (Chopard et al. 1998), such as porous media (Chen et al. 1991) and granular media (Krolyi and Kertsz 1994), among others (Boghosian et al. 1996). In addition, from the analysis of FHP microdynamics, through multiscale techniques, it is possible to obtain the traditional fluid dynamics equations (Appendix A) on a macroscopic scale (Frisch et al. 1986). These facts motivate the study of FHP as an alternative methodology for fluid simulation.

FHP is a two-dimensional model and can be seen as an abstraction, on a microscopic scale, of a fluid. The FHP describes the motion/interaction of particles in a discretized space in a hexagonal lattice, as seen in Fig. 1.

The microdynamics of FHP are given in terms of Boolean variables that describe the number of occupancy at each node of the lattice at each interaction step (i.e., the presence or not of particle). The particles move in discrete time steps, with a constant velocity in modulus, pointing along one of the six directions of the lattice. No more than one particle can move to the same lattice node, at a given instant, in a given direction. Such a constraint is called the exclusion principle, which ensures that six Boolean variables for each lattice node are sufficient to represent the microdynamics.



Lattice Gas Cellular Automata for Fluid Simulation, Fig. 1 The lattice of FHP model

Each particle moves at a constant velocity in modulus, in such a way that, in each interaction it traverses one edge of the lattice and reaches the neighboring node. In the absence of collisions, the particles keep moving along the direction specified by their velocity vector. Collisions occur when particles enter the same node at the same instant, resulting in a new local distribution of particle velocities.

When exactly two particles are incident on the same node with opposite velocities, both are deflected by an angle of 60° so that after the collision a new configuration is also made with zero momentum. Such a deviation may occur clockwise or counterclockwise, as shown in Fig. 2. For reasons of symmetry, the two possibilities are chosen randomly, with equal probability. When exactly three particles with velocities at an angle of 120° collide, each of them returns, toward the initial edge, as shown in Fig. 2. In this way, the moment remains null and is therefore preserved. For other configurations, the particles continue their movement as if there was no collision.

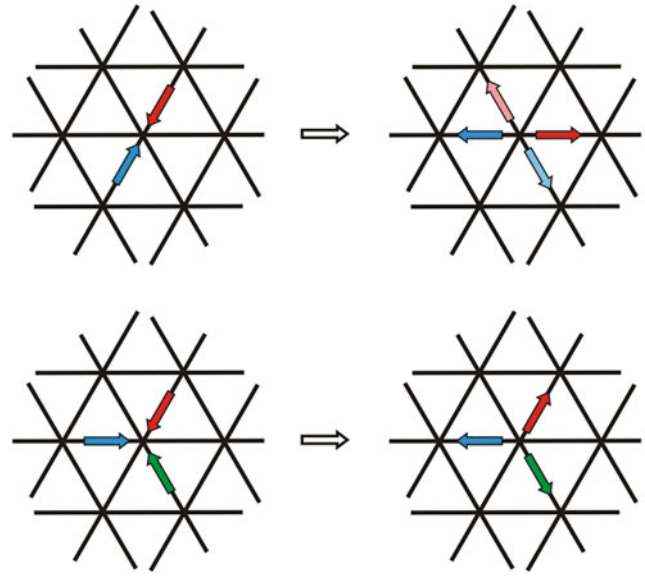
The FHP Microdynamic

The complete microdynamics of the FHP model can be expressed by an evolution equation for the occupation numbers, defined as the number $n_i(\mathbf{x},t)$ of particles entering the node $\mathbf{x}$ at instant t with velocity in the direction $\mathbf{c}_i$ (Chopard and Droz 1998):

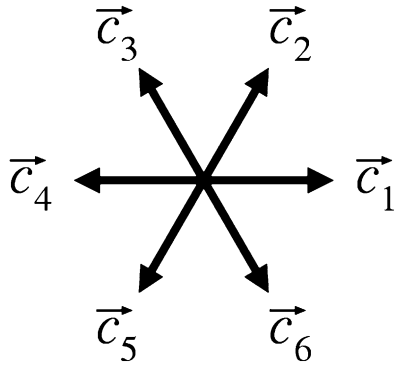
$$\mathbf{c}_i = \left(\cos\left(\frac{2\pi(i-1)}{6}\right), \sin\left(\frac{2\pi(i-1)}{6}\right)\right), \tag{1}$$

where $i = 1,\ldots,6$ represents the six possible directions for each lattice node, as shown in Fig. 3.

The numbers n_i can be 0 or 1, that is, presence or not of particle in the $\mathbf{c}_i$ direction of the lattice. Also defined is the time step as Δ_t and the



Lattice Gas Cellular Automata for Fluid Simulation, Fig. 2 Particle collisions in the FHP model



Lattice Gas Cellular Automata for Fluid Simulation, Fig. 3 Directions of movement in FHP lattice

displacement between lattice nodes as Δ_x. Thus, the six possible velocities $\mathbf{v}_i$ of the particles are related to their directions of motion by:

$$\mathbf{v}_i = \frac{\Delta_x}{\Delta_t}\mathbf{c}_i. \tag{2}$$

If there is no interaction between particles, the evolution equation for n_i can be written as (Chopard et al. 1998):

$$n_i(\mathbf{x} + \Delta_x\mathbf{c}_i, t + \Delta_t) = n_i(\mathbf{x}, t). \tag{3}$$

The Eq. 3 says that a particle entering the node $\mathbf{x}$ with velocity along $\mathbf{c}_i$ will continue in a straight line, in such a way that at the next instant it will enter the node $\mathbf{x} + \Delta_x\mathbf{c}_i$ with the same direction of motion (Chopard et al. 1998). However, when a collision occurs, one particle may be removed from its original direction or may be diverted to another. Let us look at the example of the collision described in Fig. 2, where exactly two particles compete for the same node with opposite velocities (top of the figure). In this case, before the collision, only n_2 and n_5 has 1 value in the $\mathbf{x}$ node. After the collision, we have two possibilities: n_1 and n_4 or n_3 and n_6 will have 1 value.

Generalizing for the collision between two particles with opposite velocities, the particle moving with velocity $\mathbf{v}_i$ before the collision will move with velocity $\mathbf{v}_{i-1}$ or $\mathbf{v}_{i+1}$, after the collision, where $i = 1,\ldots,6$ (note that operations on the index i must return values between 1 and 6). The binary quantity:

$$D_i = n_i n_{i+3}(1 - n_{i+1})(1 - n_{i+2})(1 - n_{i+4}) \times (1 - n_{i+5}) \tag{4}$$

indicates that a collision will occur when $D_i = 1$.

In fact, if there is a particle in direction $\mathbf{c}_i$ and one in direction $\mathbf{c}_{i+3}$, the term $n_i n_{i+3}$ will be 1. Thus it suffices that there is no particle in the other directions to ensure $D_i = 1$. Thus $n_i - D_i$

is the number of resultant particles in the $\mathbf{c}_i$ direction due to a collision of two particles along this direction.

However, when $n_i = 0$, a new particle may appear in direction $\mathbf{c}_i$, as a result of a collision between n_{i+1} and n_{i+4} or a collision between n_{i-1} and n_{i+2}. At this point, it is convenient to introduce a random Boolean variable $q(\mathbf{x}, t)$, whose value is used to decide whether a particle will be reflected to the right ($q = 1$) or to the left ($q = 0$). Thus, the number of particles created in $\mathbf{c}_i$ direction is given by:

$$qD_{i-1} + (1-q)D_{i+1}. \tag{5}$$

For the case shown in Fig. 2 of a collision between three particles, they can be scattered, with one of them occupying the direction $\mathbf{c}_i$. The amount (T) expressing the occurrence of a collision between three particles n_i, n_{i+2}, and n_{i+4} can be obtained by following the same principles above, given by:

$$T_i = n_i n_{i+2}\, n_{i+4}(1-n_{i+1})(1-n_{i+3}) \times (1-n_{i+5}). \tag{6}$$

Analogous to the previous case, the result of a collision between three particles is modify the number of particles in the direction $\mathbf{c}_i$. Thus, the number of resulting particles in $\mathbf{c}_i$ direction, considering the disappearance of a particle due to collision at position i or the appearance of a particle due to collision at position $i + 3$ can be expressed by:

$$n_i - T_i + T_{i+3}. \tag{7}$$

Once the collision rules have been stipulated, we can rewrite the Eq. 3 to the microdynamics of the FHP as:

$$n_i(\mathbf{x} + \Delta_x \mathbf{c}_i, t + \Delta_t) = n_i(\mathbf{x}, t) + \Omega_i(n(\mathbf{x}, t)), \tag{8}$$

where Ω_i is the collision term, defined from expressions (5) and (7):

$$\Omega_i = -D_i + qD_{i-1} + (1-q)D_{i+1} - T_i + T_{i+3}. \tag{9}$$

The Eq. 8 can be easily implemented, and the FHP model can be efficiently simulated in a computer. More elaborate collision operators can be created by including collisions between four particles or even by inclusion of a resting particle (Frisch et al. 1987). In general, the only constraint imposed is that the collision operator Ω_i preserves the mass $\sum_{i=1}^{6} \Omega_i = 0$ and the moment $\sum_{i=1}^{6} \mathbf{v}_i \Omega_i = 0$..

The Macroscopic Quantities

The physical quantities of interest are not the Boolean variables but the macroscopic quantities or the mean values, such as density and linear momentum at a point in the system (Chopard and Droz 1998). The distribution below corresponds to the probability of having a particle in the node $\mathbf{x}$, at instant t, with velocity $\mathbf{v_i}$ defined by the Eq. 2 (Chopard et al. 1998).

$$N_i(\mathbf{x}, t) = \langle n_i(\mathbf{x}, t) \rangle, \quad i = 1, \ldots, 6. \tag{10}$$

In general, an LGCA model is characterized by the z number of directions for each node of the lattice and the spatial dimension d. For a rectangular lattice with $d = 2$, we have $z = 4$, whereas for a hexagonal lattice we have $z = 6$. In some models there is the addition of a direction ($\mathbf{c}_0$), where $n_0 \in \{0, 1\}$ will be the number of particles at rest ($\mathbf{v}_0 = 0$) (Chopard and Droz 1998).

Following the usual definition of statistical mechanics, the local density of particles is the sum of the means of microscopic variables (expression 10):

$$\rho(\mathbf{x}, t) = \sum_{i=1}^{z} N_i(\mathbf{x}, t). \tag{11}$$

Similarly, the linear momentum ($\rho \mathbf{u}$) is given by (Chopard and Droz 1998):

$$\rho(\mathbf{x}, t)\mathbf{u}(\mathbf{x}, t) = \sum_{i=1}^{z} \mathbf{v}_i N_i(\mathbf{x}, t). \tag{12}$$

From these definitions and conservation laws, it is possible to estimate the macroscopic behavior of the system. For this, the multiscale expansion of Chapman-Enskog is used. The details of this technique can be found in the work of (Frisch et al. 1986). The result is the obtaining of mass and Navier-Stokes conservation equations from the microscopic dynamics of the FHP described in this section.

Mathematical Foundations

Conservation Laws

The most general conservation principles are the laws of mass conservation, moment, and the first and second laws of thermodynamics. Assuming that matter cannot be destroyed or created and despising sources, the amount entering a volume element equals the quantity that exits plus the amount accumulated in the element. This principle can be expressed in terms of transfer rates:

$$\text{Input rate} = \text{output rate} + \text{accumulation rate}.$$

The following is a review of the principles of mass conservation and movement. Initially, the general expressions of these laws will be developed for scalar and vector fields and then applied to the specific case of fluid mechanics.

Conservation Laws for Scalar Fields

Let U be a scalar quantity per unit volume, defined in an arbitrary volume Ω, fixed in space, and bounded by a closed surface S. The variation of the local intensity of U occurs due to the flow acting which expresses the contribution of the external medium to Ω and the Q sources. The general form of the conservation law for the scalar quantity U can be written as (Hirsch 1988):

$$\frac{\partial}{\partial t}\int_{\Omega} U d\Omega + \oint \mathbf{F}\cdot d\mathbf{S} = \int_{\Omega} Q_V d\Omega + \oint_{S} \mathbf{Q}_S \cdot d\mathbf{S}. \quad (13)$$

In Eq. 13, the first term to the left of the equality sign represents the U variation within the volume Ω per unit time. Such variation must be equal to the contribution of external medium due to the flow through the surface S, given by:

$$-\oint \mathbf{F}\cdot d\mathbf{S}, \quad (14)$$

plus the contributions of volumetric (Q_V) and surface ($\mathbf{Q}_S$) sources of U, expressed, respectively, by the terms to the right of the equal sign in the Eq. 13.

Assuming continuity of flow and surface sources, one can use the Gaussian theorem, also known as the divergence theorem, and rewrite the expression (13) as:

$$\int_{\Omega}\frac{\partial U}{\partial t}d\Omega + \oint_{\Omega}\nabla\cdot\mathbf{F} = \int_{\Omega} Q_V d\Omega + \oint_{\Omega}\nabla \cdot \mathbf{Q}_S d\Omega. \quad (15)$$

Equation 15 is in the integral form of the conservation law. The differential form is obtained directly from this, assuming any volume, and is given by:

$$\begin{aligned} &\frac{\partial U}{\partial t} + \nabla\cdot\mathbf{F} = Q_V + \nabla\cdot\mathbf{Q}_S \Rightarrow \\ &\frac{\partial U}{\partial t} + \nabla\cdot(\mathbf{F}-\mathbf{Q}_S) = Q_V. \end{aligned} \quad (16)$$

Conservation Laws for Vector Fields

For the case where the conserved amount is described by a vector quantity $\mathbf{U}$, then the flow and the term relative to the surface sources become tensors, $\overline{\overline{F}}$ and $\overline{\overline{Q}}_S$, respectively, and the term corresponding to the volumetric sources becomes a vector $\mathbf{Q}_V$. Equations 15 and 16, respectively, assume the form (Hirsch 1988):

$$\int_{\Omega} \frac{\partial \mathbf{U}}{\partial t} d\Omega + \oint_{\Omega} \nabla \cdot \overline{\overline{F}} d\Omega = \int_{\Omega} \mathbf{Q}_V d\Omega + \oint_{\Omega} \nabla \cdot \overline{\overline{Q}}_S d\Omega, \quad (17)$$

$$\frac{\partial \mathbf{U}}{\partial t} + \nabla \cdot \left(\overline{\overline{F}} - \overline{\overline{Q}}_S \right) = \mathbf{Q}_V. \quad (18)$$

Mass Conservation Equation

The partial differential equation that expresses conservation of mass is also known as the continuity equation. Applying the conservation law given by the Eq. 15 for the particular case where U is the mass density density (ρ), we have:

$$\int_{\Omega} \frac{\partial \rho}{\partial t} d\Omega + \oint_{\Omega} \nabla \cdot (\rho \mathbf{v}) = \int_{\Omega} Q_V d\Omega + \oint_{\Omega} \nabla \cdot \mathbf{Q}_S d\Omega, \quad (19)$$

where $\mathbf{v}$ is fluid velocity. In the differential form, we have:

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) = Q_V + \nabla \cdot \mathbf{Q}_S. \quad (20)$$

In the absence of sources, the continuity equation takes into account only the density and velocity of the fluid. It can be applied to all fluids, compressible and incompressible and Newtonian and non-Newtonian (Shaughnessy et al. 2005). For incompressible fluids, the density is constant, that is, it is not a function of the spatial coordinates nor of the time. The Eq. 20 results in:

$$\nabla \cdot \mathbf{v} = 0. \quad (21)$$

Another particular case occurs when the density is independent only of time, resulting in:

$$\nabla \cdot (\rho \mathbf{v}) = 0. \quad (22)$$

Moment Conservation Equation

The linear momentum, defined by ($\rho \mathbf{v}$), is a vector quantity, and therefore its conservation law has the general form given by Eqs. 17 and 18. The central issue now is to determine the tensors $\overline{\overline{F}}$ and $\overline{\overline{Q}}_S$ and the vector $\mathbf{Q}_V$ that appear in these equations.

By Newton's second law, it is known that the agents responsible for the linear momentum of a physical system are the forces acting on it. Such forces may be external or internal. Let us then consider a portion of fluid bounded by a surface S.

As external forces, we can have force fields such as the gravitational field and electromagnetic field. Let $\mathbf{f_e}$ be the volumetric density of the resultant of these forces. In addition to external forces to the system, we also have internal forces due to deformations and internal tensions of the same. In this text, it is assumed that the fluid is Newtonian, that is, that the internal stresses are given by the expression (Hirsch 1988):

$$\overline{\overline{\sigma}} = -p\overline{\overline{I}} + \overline{\overline{\tau}}, \quad (23)$$

where $\overline{\overline{I}}$ is a unit tensor, p is the hydrostatic pressure, and $\overline{\overline{\tau}}$ is the tensor of tensions whose components are given by (Hirsch 1988):

$$\tau_{ij} = v\left[\left(\partial_i v_j + \partial_j v_i \right) - \frac{2}{3} (\nabla \cdot \mathbf{v}) \delta_{ij} \right], \quad (24)$$

where v is the kinematic viscosity.

By integrating (23) along S, we have the resultant of the internal forces to the fluid that act on the volume Ω. As for the tensor $\overline{\overline{F}}$, this will be given by (Hirsch 1988):

$$\overline{\overline{F}} = \rho \mathbf{v} \otimes \mathbf{v}, \quad (25)$$

where:

$$\mathbf{v} \otimes \mathbf{v} = \begin{pmatrix} v_1 v_1 & v_1 v_2 & v_1 v_3 \\ v_2 v_1 & v_2 v_2 & v_2 v_3 \\ v_3 v_1 & v_3 v_2 & v_3 v_3 \end{pmatrix}, \quad (26)$$

with $\mathbf{v} = (v_1, v_2, v_3)$.

Thus, the expression (17) takes the form:

$$\int_{\Omega} \frac{\partial(\rho \mathbf{v})}{\partial t} d\Omega + \oint_{\Omega} \nabla \cdot (\rho \mathbf{v} \otimes \mathbf{v}) d\Omega = \int_{\Omega} \rho \bar{f}_e d\Omega + \oint_{S} \bar{\bar{\sigma}} d\mathbf{S}. \quad (27)$$

Substituting $\bar{\bar{\sigma}}$ with the expression (23) gives the integral form of the conservation law of linear momentum for a Newtonian fluid. The corresponding differential expression is obtained directly from the integral form, given by (Hirsch 1988):

$$\frac{\partial(\rho \mathbf{v})}{\partial t} + \nabla \cdot \left(\rho \mathbf{v} \otimes \mathbf{v} + p\bar{\bar{I}} - \bar{\bar{\tau}} \right) = \rho \bar{f}_e. \quad (28)$$

Subtracting the Eq. 20 from the left side of the Eq. 28, multiplied by ρ, and assuming the source terms are null, we find:

$$\rho \frac{D\mathbf{v}}{Dt} = -\nabla p + \nabla \cdot (\bar{\bar{\tau}}) + \rho \bar{f}_e, \quad (29)$$

where $D\mathbf{v}/Dt$ is the material derivative, given by:

$$\frac{D\mathbf{v}}{Dt} = \frac{\partial \mathbf{v}}{\partial t} + \mathbf{v} \cdot \nabla \mathbf{v}. \quad (30)$$

When the expression (24) for the tensor of tensions of a viscous Newtonian fluid is replaced in Eq. 29, we obtain what we call **Navier-Stokes equations**. For constant viscosity coefficients, this equation reduces to:

$$\rho \frac{D\mathbf{v}}{Dt} = -\nabla p + v \left[\Delta \mathbf{v} + \frac{1}{3} \nabla (\nabla \cdot \mathbf{v}) \right] + \rho \bar{f}_e. \quad (31)$$

For incompressible fluids ($\nabla \cdot \mathbf{v} = 0$), the Eq. 31 reduces to:

$$\rho \frac{D\mathbf{v}}{Dt} = -\nabla p + v \Delta \mathbf{v} + \rho \bar{f}_e. \quad (32)$$

In the case of an ideal fluid without internal stresses, and therefore without viscosity $v = 0$, the Eq. 32 reduces to the call **Euler equation**:

$$\rho \frac{D\mathbf{v}}{Dt} = \rho \frac{\partial \mathbf{v}}{\partial t} + \rho (\mathbf{v} \cdot \nabla) \mathbf{v} = -\nabla p + \rho \bar{f}_e. \quad (33)$$

Therefore, we find the equations of mass conservation and Navier-Stokes, given, respectively, by:

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) = Q_V + \nabla \cdot \mathbf{Q}_S \quad (34)$$

$$\rho \frac{D\mathbf{v}}{Dt} = -\nabla p + v \left[\Delta \mathbf{v} + \frac{1}{3} \nabla (\nabla \cdot \mathbf{v}) \right] + \rho \bar{f}_e. \quad (35)$$

Such equations form the basis for describing the behavior of a fluid, particularly for computer graphics animations.

Synonyms

Action-adventure game; open-world game

Definitions

Action-adventure game = a video game that combines elements from both action game and adventure game.

Open-world game = a video game featuring a virtual world in which the player can explore and play freely without linear and structured gameplay.

The Lens of Curiosity

The Legend of Zelda: Breath of The Wild is a game where the players' curiosity can change their path and the way they think of the worlds' origins. When playing Breath of the Wild players can easily find themselves climbing tall mountains and staring into the distance wondering what that other mountain could hold or what this oddly shaped rock may be. The way Breath of the Wild can bend players' minds is very intriguing.

In Jesse Schell's book *The Art of Game Design: A Book of Lenses*, the Lens of Curiosity states that "to use this lens, think about the player's true motivations — not just the goals your game has set forth, but the reason the player wants to achieve those goals." (Schell, 2019) The Lens of Curiosity requires us to ask the following these questions:

1. What questions does my game put into the player's mind?
2. What am I doing to make them care about these questions?
3. What can I do to make them invent even more questions?

At the start of the game The Legend of Zelda: Breath of The Wild, the main character Link awakens from a slumber and walks out of a cave to find this massive and expansive world that makes the player think, "What's in this huge world, where is everyone, and how do I start pursuing this world?" Every so often the game throws something that can catch a curious gamer's eye; like a sparkle off the side of a road or a bright beacon being shot into the sky. These moments are what really make the game's world so immersive and give the player a variety of things to do. For example, there are these creatures known as the Korok that give the player a Korok Seed that can be used to expand Link's inventory by giving him more slots to store weapons, items, etc. These seeds can be found by solving puzzles or just flat out finding them by flipping over rocks or shooting specific objects with Link's bow. Giving the player the choice to find these leads to the player asking, "Will finding these benefit me or just be a waste of time?" There is also a story behind the world and why it has been cleansed of most of its people and why a lot of the land is in ruins.

At the start of the game, the player is given the option to head straight to the final boss of the game, and while they can do this, it makes the game way harder for the player and leaves the player with more questions than answers when they beat the final boss. They are also given the option to go to a character named Impa that will lead them on a path to experience the world more and dive deeper in the past that Link has experienced.

Sure the player can beat the game right off the bat, but what about the rest of the world? Should they become stronger and master the games mechanics, maybe experience more of Link's memories? It is all up to the player. The player cares about these questions the further they get into the game, giving the player crucial choices that can leave the player on the brink of survival or on the path to destroying the evil Calamity Ganon.

The player's mind is what turns this game into an experience. Players find themselves experiencing more and more of the world by solving a question they asked maybe a couple hours earlier. These are just some of the questions the player will ask themselves as they play Breath of the Wild. With so much to uncover in the world and so many things to experience, one could say there is nearly an infinite amount of questions. Ultimately, Breath of the Wild asks the player how they will go about choosing a path in this expansive world. Where and how high will the player set their stakes and why are they setting them where they are?

Digital communication; Life-size telepresence; Telepresence

Definition

Telepresence technology refers to using a communication medium to give the impression of being present in an environment. Advancements in modern communication, media, and Internet have allowed for the widespread adoption of this technology. Using this technology can help to save both time and money while also reducing environmental damage because it can be used as an alternative to traveling to present at conferences or other meetings. Telepresence systems have the potential to make it easier for individuals who are separated by distance to communicate with one another.

It can be helpful in the world of business, education, and medicine, for example, allowing nonexperts to perform complicated tasks under the guidance of professionals. A user's size has been found to significantly influence the outcomes of human communication aspects. If the user is displayed in life size, there is a good chance that social relationships, for example, power or dominance and persuasiveness, will be more evenly distributed and natural. Therefore, this entry discusses life-size telepresence and other technologies such as videoconferencing and holographic telepresence.

Introduction

Telepresence is a technology that allows the user to feel present at a specific location when he remotely transfers himself through digital representation (Fadzli et al. 2020). It uses a technique that utilizes necessary multimedia such as sounds, visions, and touch to create a sense of physical presence at remote locations (Shen and Shirmohammadi 2006). Telepresence is also known as virtual representation, where the term "tele" in telepresence refers to telecommunication technology (Kittler 2021), and the term "presence" in telepresence refers to the experience of existing in one place or environment (Witmer and Singer 1998).

Figure 1 shows the timeline progress of the telepresence system from Fadzli et al. (2020)).

Life-Size Telepresence and Technologies, Fig. 1 Chronological progress of telepresence (Fadzli et al. 2020)

According to the timeline, the early phase of telepresence is the virtual space teleconferencing using a lot of cameras to acquire the photometric and depth information (Fuchs et al. 1994). Three years after, Kanade et al. (1997)) constructed a virtual world from real scenes for the viewer to view continuous motion in a virtual sequence. However, there are discontinuities in virtual image motion. Thus, Mulligan and Daniilidis (2000)) proposed view-independent scene acquisition for telepresence. Furthermore, Towles et al. (2002)) provided the 3D telecollaboration over Internet2 because the view-independent scene acquisition required transmission of rendered 3D world. However, there is a hardware restriction and limitation on the display setup, making Tanikawa et al. (2005) introduce real-time and real-size transmission and presentation of a human figure. In this the person's image is captured by multiple cameras, transmitted through the network, and displayed on a revolving flat panel (Tanikawa et al. 2005). However, the issues did not stop here. There are overlapped between the viewer and the display system. Hence, Kurillo et al. (2008) produced an immersive 3D environment for remote collaboration and training of physical activities that are able to perform real-time 3D construction of users.

Life-Size Telepresence

Telepresence space can support nonverbal communication such as body language, eye gaze, and facial expression because it has a free viewpoint video combined with immersive projection technology (Fairchild et al. 2016). Besides that, it allows users to do so in such a way that users have the same transparent sense of appropriateness of space to activity. One of the examples of telepresence space by Beck et al. (2013) is in which there is a telepresence space where two groups of users meet virtually in a life-size 3D representation of the remote user. Figure 2 shows an example of a remote user in telepresence space.

One of the issues of concern is telepresence using holoportation technology (Orts-Escolano et al. 2016) requires the user to wear HMD in telepresence space. The use of cumbersome hardware such as HMD limits face-to-face communications (Regenbrecht et al. 2004). The small display optic in front of each eye in HMD and narrow field of view (FOV) make the device have a limitation for gaze input in face-to-face communications. Besides that, wearing HMD can be very uncomfortable for participants. According to Kooi et al. (Kooi and Toet 2004), binocular display systems such as HMD shows a different image to the left and right eye, which can affect viewing comfort. Users feel discomfort and have motion sickness. Figure 3 shows an example of telepresence space using HMD and performing remote collaboration.

The uncanny valley (MacDorman and Chattopadhyay 2016) is a phenomenon that occurs when human replicas stimulate unintended cold, eerie emotional responses in viewers. The effect was first proposed in 1970 by Masahiro

Life-Size Telepresence and Technologies, Fig. 2 Telepresence space with a remote user

Mori, who associated it with discrepancies in the replica's realism, with some features represented as human and others as nonhuman (Mori 1970). According to Jones et al. (2021), the uncanny valley of telepresence is characterized by a sharp drop in the continuous increase of both local and remote users' experience of belonging as a telepresence experience becomes more like a physical presence. Yu et al. (2021) argue that overcoming the "Uncanny Valley of Telepresence" will entail identifying the gestalt of what is most accountable about the comfort of belonging with others. Based on their findings, there is a similar concept of the uncanny valley of telepresence, which states that the higher the simulation level of a telepresence experience, or the more it tries to simulate or replicate actual presence, the greater the user's feeling of "belonging to the space," up to a turning point. The user's experience begins to decline at this point. The illusion of "being there" raises the expectations of their own abilities in the space, but when those expectations are not met, they become frustrated and believe they are not meant to be there. In other words, they have a diminished sense of "belonging" there.

Life-Size Telepresence and Technologies, Fig. 3 3D teleportation remote collaboration in real time

Yu et al. (2021) propose a different interpretation of uncanny valley related to telepresence, claiming that the level of coherence may have influenced the perception of the remote participants perceiving the presented avatar. For example, MacDorman and Chattopadhyay (2016) claim that decreasing consistency in human realism in avatar images increases the perception of uncanny valley categories. A similar aspect could be argued for their study; while the 3D virtual character avatar was not entirely out of consistency with the environment, it is clear that the point cloud representation avatar was exactly fitting the style and presentation of the environment reconstruction, as the same system was used for the avatar and for the environment. The result shows that in order to choose the representation of the user, we need to consider the way the environment was represented as well.

Telepresence can be projected in many sizes, either small or large. In order to achieve a great augmented reality collaboration environment, life-size telepresence can be considered the perfect size. Life-size telepresence has the same measurement as a real-life size. This will help the participants to feel more realistic and feel presence in the remote location as according to Pejsa et al. (2016).

Based on Mark and DeFlorio (2001) research, the large ratio of life-size telepresence supports the interaction for both sites. When the interaction between each side is supported, both participants have a better experience in communication through the projection of holograms based on the experiment that has been conducted where there are two groups of people; group A sat in Room A and watched the projection of group B in Room B. Besides that, Pejsa et al. (2016) have claimed that life-size telepresence makes the participants appear as if they are inhabiting the same space. This facilitates more natural interaction since people can fully see each other and improve nonverbal signals such as gaze, body language, and gestures. The life-size virtual copies of remote participants are projected into physical space, as shown in Fig. 4.

Comparison Between Telepresence and Videoconference

This section shows the difference between audioconferencing, videoconferencing, and telepresence. Videoconferencing began in 1964 when AT&T unveiled the picturephone at the New York World's Fair, the world's first videoconferencing endpoint. In the year 2000, telepresence systems hit the market, bringing a more realistic approach to face-to-face meetings. However, they are not

Life-Size Telepresence and Technologies, Fig. 4 Augmented image in life-size telepresence

concerned with price but rather with providing customers with a high-quality, fully immersive experience (Pulido 2011). This shows that videoconference exists before telepresence and that telepresence is the advanced technology where it produces a better quality of video and facial expression of the user. In comparison, videoconferencing produces low to medium video resolution and displays in TV quality.

In recent years, real-time telepresence has attracted more and more attention. However, this technology has several issues that cannot be avoided. One of the issues is that participants must travel to facilities that are equipped and staffed to produce telepresence videoconferences (Fuchs et al. 2014). This is an issue for the user that is traveling. They need to find a place that has the equipment of the telepresence or prepare the set of the telepresence equipment at their place.

Although the risk of disruption or failure is extremely low, it is always possible over the Internet (Takamizawa et al. 2004). Coverage of the Internet depends on the location of the user. If the user location has low coverage of the Internet, the possibility for failure over the Internet is high. Users cannot perform telepresence without the Internet. Disruption Internet also can occur during telepresence. The comparison table is produced by Davis and Kelly (2008). Table 1 lists a comparison of three terminologies based on their characteristics, videoconferencing, HD videoconferencing, and telepresence.

Technologies

This section will discover the technologies used for telepresence.

Videoconferencing

Telepresence has brought a revolution in the communication industry. The advancement of telepresence technology has changed the way we are able to communicate and connect with each other. One of the advancements of telepresence technology is videoconference technology. Telepresence technology is a system that provides a life-size, high-definition video and stereo-quality audio, and make people experience face-to-face interaction at a distance (Pulido 2011). Figure 5 shows an example of videoconference technology, and this type of technology is very common in a meeting room.

Holographic

The next technology is holographic telepresence technology. Holographic technology provides full motion of projection, as well as realistic and 3D images in real-time. As stated by Luevano et al. (2019), a holographic telepresence system captures and compresses images of real, remote people or surrounding objects and transfers images together with the sound across the Internet. Holographic use the method of recording patterns of light and projecting the pattern in a three-dimensional image

Life-Size Telepresence and Technologies, Table 1 Comparison of the three terminologies

Characteristic	Videoconferencing	HD videoconferencing	Telepresence
Cost	Free to $100 s	$1000s	$10 k to $100ks
Picture quality	Poor to good	Good to excellent	Excellent
Bandwidth requirement per endpoint	100 s of kilobits per second	100 s of kilobits per second to megabits per second	1 Mbps to 50 Mbps+
No. of participants	Usually two	Two or more	Many
Interoperability with other systems	Common	Limited	Very limited
Camera position	Fixed or variable	Fixed or variable	Usually fixed
Room footprint	Variable	Variable	Fixed and requires room preparation
Platform	Software and hardware	Usually hardware	Hardware

called hologram (Elmorshidy 2010), and Fig. 6 shows the example of holographic projection.

Other than that, the projector camera is also another type of telepresence technology. This technology has the potential for remote individuals to view each other's environment and also communicate by overlaying the user's virtual copy image in new ways into the remote location,

Life-Size Telepresence and Technologies, Fig. 5 Example of videoconferencing

Life-Size Telepresence and Technologies, Fig. 6 Holographic telepresence using projector-based images

Life-Size Telepresence and Technologies, Table 2 Comparison of the three terminologies

Type	Advantages	Disadvantages
High-definition	High resolution	Flat images
3D display	High-resolution Stereoscopic	Narrow viewing angles Require glasses to display Not in 3D imagery
3D holographic display	"Life-like" picture Volumetric 3D display Interactivity	Require a large amount of processing Constraint by the size of holographic material Production cost is expensive

without wearing any specialized device on the user (Pinhanez and Pingali 2004). Projector-camera-based technology by Pinhanez et al. (Pinhanez and Pingali 2004) is much more simple than holographic. The cost required for application setup is also low and suitable for telepresence.

Table 2 shows the advantages and disadvantages between high-definition, 3D displays, and 3D holographic display. Based on the table, 3D holographic displays have a lot of advantages compared to other technology. However, the production cost to set up a holographic is expensive.

Augmented reality; Live texturing; Texture mapping

Definition

Nowadays, many coloring books have been using augmented reality (AR) as the enabler to display virtual objects in the real world. Real-time texture mapping is an essential element that brings AR coloring more advanced. The augmented 3D character is textured according to the video stream coloring. Act as a guideline to deliver real-time texturing mapping for augmented reality coloring applications. This entry explains the live texturing process in AR, the live texture mapping for the AR coloring book.

Introduction

AR is growing not just in entertainment but also in education. AR books are a product that uses AR technologies and becomes new development of entertainment and educational models.

An interactive augmented coloring book introduced by Clark et al. (2012) is additionally one of the real leaps forward of AR education. The technology features the significance of direct intuitiveness with the content by enabling the user to control the result AR 3D content with their shades of shading, giving more impact on the learning strategy since interactivity promotes learning by activating specific cognitive processes (Nor'a et al. 2019).

AR books can become physical or digital copies with both text and illustrations. Technology usage, such as smartphones or tablets, can display the 3D content on top of the AR book. This augmentation can be achievable once the camera points toward the page of the AR Book. Usually, the AR Book will provide the mobile application to be downloaded by the smartphone that allows the application to track the page and display the content based on the page that we track. A video clip, audio clip, image, or even 3D object can become one of the AR content that the AR Book can display.

HITLab NZ. ColAR has researched the idea of the AR book for more than 10 years which allows users to color the book page and view the 3D model in the real world with colored textures (Cho et al. 2016). Usually, the AR color book requires a paper book and smartphone application to use with the AR book. The user needs to color the paper book first before the texture is mapped onto a 3D character and displayed in an AR environment. With the AR coloring book, the children can view 3D animation of the character and painted color when they use a smartphone to take real-time video.

Quiver created a ColAR application that already sells coloring page through the online market, and users can download the application from the apps store to view 3D characters in the AR environment after they color it. The Korea-based company AIARA also produces an AR coloring book that combines the AR and Internet of Things (IoT), allowing the merge of analogue and digital media.

Live Texture Mapping in AR

Earlier work has been found in Clark et al. (2012) when they create scenes in 3D and textured models that refer to user creation. After that, actual book pages will become the base for placing the 3D content in the real world. With this, the user can feel a 3D experience with their content. Figure 1 shows the two examples of the AR character as 3D content on top of the page. In 2015, the enhancement suggested a live texturing process, and it has been defined in Magnenat et al. (2015) as illustrated in Fig. 2. As described in Zhao et al. (2017), it presented a texture process that generates a texture map for 3D augmented reality characters from 2D colored drawings using a lookup map. Considering the movement of the mobile device and drawing, they have given an efficient method to track the drawing surface.

Figure 2 shows the adapted pipeline defined in Magnenat et al. (2015) of the static content creation and live surface tracking, texturing, and rendering pipelines. The pipeline has stated that it needs to be run only once. A live pipeline tracks the drawing and overlays the augmented character on top of it, with a texture created from the drawing in real-time using the lookup map. As in Fig. 2, in the Live Pipeline box, the camera image captures a set of colored drawing pages. Five boxes have been running through, and the following points described all the processes involved:

- **Image Processing**. The input image converts the colored page into grayscale and uses image processing to produce drawing lines. The black line has been produced by applying adaptive thresholding. Figure 3 shows the process involved.

Live Texture Mapping in Handheld Augmented Reality Coloring Book, Fig. 2 Live texturing pipeline in AR Color Book

- **Template selection**. It shows the content pipeline where the UV mapping has been implemented to quickly patch the image into characters so their textures will correspond to what has been drawn. Here it is called a real-time painting.
- **Surface tracking**. The template that has been selected needs to retrieve the reference images,

and this surface tracking will align the camera with the captured image to render the reference image.

- **Texture creation and mesh rendering**. Used when to open the camera, there will be a real live environment as a background image for AR scene, and pose estimation to render the 3D scene with the live texture mapping in real-time.

Image Inpainting Technique

Image inpainting is defined as a process to restore the damaged area of the image. Several kinds of research have been done to reconstruct images from message overlay or scratches, loss concealment in an image, and occlusion problem when rendered after the camera captured the image (Casas et al. 2017). Marker hiding has been studied to hide markers when the camera tracked the marker (Korkalo et al. 2010).

In image inpainting, there are still some problems concerning ill-posed inverse issues with no well-defined unique solution. It is necessary to define image priors to solve the problem. This method assumes the pixel from the known and unknown parts to have the same measurable properties or geometrical complexes. From that point onward, this will be converted into various local or global priors to have an inpainted image as physically logical and visually satisfying as expected (Guillemot and Le Meur 2013). The diffusion-based inpainting method denotes the image's unknown part and fills in with the source from the known region. These methods are generally relevant for accomplishing straight lines and curves and inpainting small areas conceivable (Guillemot and Le Meur 2013).

The term diffusion comes from using the smoothness priors, which come from proliferating nearby data by analogue with physical marvels like warmth proliferation in physical structures and smoothness constraints. Inpainting utilizing dispersion easily spreads nearby picture structures from the outside to the inside of the gap, "emulating" the motion of expert painting restorators (Guillemot and Le Meur 2013). It then uses the considered data to assume smoothness limitation and iteratively regularized and creates a smoother image in an endless array. However, diffusion-based is not suitable for the recovery texture of large areas, and it also tends to be a blur. The inpainting process is used only in the first frame to generate the texture instead of inpainting for every frame to ensure consistency, and then the generated texture is overlaid on the marker area according to the camera pose. Multisensory has

been recently explored instead of the diffusion-based inpainting method for AR drawing (Meesuwan 2021). However, today, an advanced diffusion-based inpainting method has been explored for real-time inpainting 4 K color images on contemporary GPUs (Kämper and Weickert 2021).

Definition

Computer Vision	Computer vision is the Artificial Intelligence (AI) system incorporated with other scientific fields, such as signal processing and neurobiology, to interpret and gain high-level understanding from digital images or videos.
Healthcare Robot	Healthcare robot refers to a machine programmed by a computer capable of assisting humans in the medical field. In addition, it is able to provide care and support to disabled patients and the elderly.

Medicine dispenser	Medicine dispenser refers to the item that releases medications at a specific time and assists elderly persons and those who may have impaired abilities to comply with their recommended medication.

Introduction

A platform with multi-terrain navigation capabilities is necessary for a healthcare robot to move through varied geographical landscapes. The locomotion feature plays a significant role. This feature allows the robot to navigate the areas, especially inside a house with many rooms. Furthermore, another significant function in healthcare is human tracking. A healthcare robot should have both locomotion and human tracking abilities to navigate an area (e.g., a house) and look for the target person or patient when it is the right time for medication.

Motivation and Background

The World Health Organization (WHO) reported that the number of disabled persons is dramatically increasing (WHO 2011). It is related to demographic changes and a rise in chronic health problems, among other factors. Therefore, scaling up disability services in primary healthcare, particularly rehabilitation therapies, is urgently required. These disabled persons require continual supervision to complete simple tasks, such as eating and drinking. Moreover, a constant monitoring process is also necessary to avoid any emergencies. As a result, it is prudent to encourage technology that aids in detecting and responding to emergency circumstances. Many camera monitoring systems for patient behavior detection are available in the market today. However, these systems could invade in-house privacy, but they also lack the function of aiding patients. Another solution is to create mobile healthcare robots to assist the patients. Healthcare robots can track the behavior of the targeted patient. The auxiliary programs, such as time scheduling, medicine detection, and digital patient's medical record, can be integrated into the healthcare robot for enhancing its capabilities.

Beyond the conventional purview of surgical and rehabilitative robots, robots perform different activities and purposes in the medical/health and social care sectors. In this scenario, the robot may navigate to search for patients inside a specific location. However, inefficient navigation in a socio-physical environment may cause the search to be delayed, identifying emergencies. Thus, computer vision techniques can aid the navigation system in healthcare robots, such as placing the patient, evading obstacles, and detecting dangerous objects. For example, a visual-based robot navigation method for the catadioptric optical system was proposed by Winters et al. (2000). They presented a method for converting images from a catadioptric camera to bird's-eye view. These images are used to control the orientation of the robot movement. In addition, a teaching and replay approach was proposed to train the robot to navigate indoor and outdoor environments (Chen and Birchfield 2006). In the teaching phase, the robot is manually guided along the desired path, and then in the playback phase the robot follows that course independently. This method allows the robot to automatically extract the feature points along the trajectory during the training phase. The advantage of this technique is it does not require any calibration on the robot's camera. However, the change in the environment can affect the robot navigation process since the feature points are also changed.

Obstacle avoidance is another issue for mobile robots. The neuro-fuzzy technique is used to construct an intelligent obstacle-avoidance approach to autonomous navigation of a mobile robot in unfamiliar surroundings (Wang et al. 2004). The robot is integrated with four infrared sensors to detect the distance from the obstacles to the robot itself. The neuro-fuzzy model then processes this distance information to determine the optimal actions to avoid the obstacles. Estimating slip angle is also a prominent issue for wheel-based robots since there are some situations where the robots need to travel through rough terrain environments. Hough transform incorporated with fuzzy logic was applied to estimate the angle of inclination of the wheel trace with respect to the

vehicle reference frame (Reina et al. 2008). It detects the deviation in the wheel trace in real time. This deviation implies that the terrain has a change of inclination angle.

Structure of Learning System

The architecture of the locomotion and human tracking system is shown in Fig. 1.

The architecture consists of four modules: image acquisition module, vision module, decision module, and robot control module. The details are presented in the following subsections.

Image Acquisition Module

The image acquisition module controls the robot cameras. Traditionally, two cameras placed horizontally apart are used to capture two different perspectives of a scene, analogous to human binocular vision. This module synchronizes video frames from two cameras, removes noisy signals, and sends the set of digital images to the vision module.

Vision Module

The vision module is the process for extracting 3D information from the set of digital images taken from two cameras. The process is illustrated in Fig. 2.

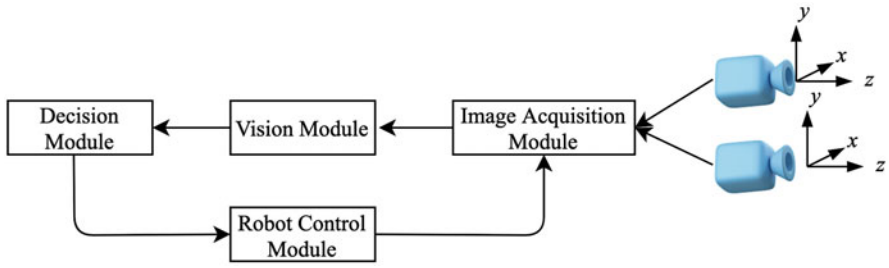
Block matching algorithm is applied to generate a disparity map that encodes the difference between corresponding picture points' horizontal coordinates from the acquired image pair (Kadri et al. 2019). The output disparity map presents the estimation of the position of features in the image pair. Then, the disparity map will be processed by a segmentation algorithm for distinguishing objects that appear in the image (Yoon et al. 2017). The disparity map segmentation image represents different objects at different distances to the robot's cameras. Next, feature extraction is applied to the disparity map segmentation to extract 2D and 3D features (Tiwari et al. 2013). These features are then used to object detection algorithms. Finally, the object detection algorithm will identify objects in the image pair (Redmon et al. 2016).

Decision Module

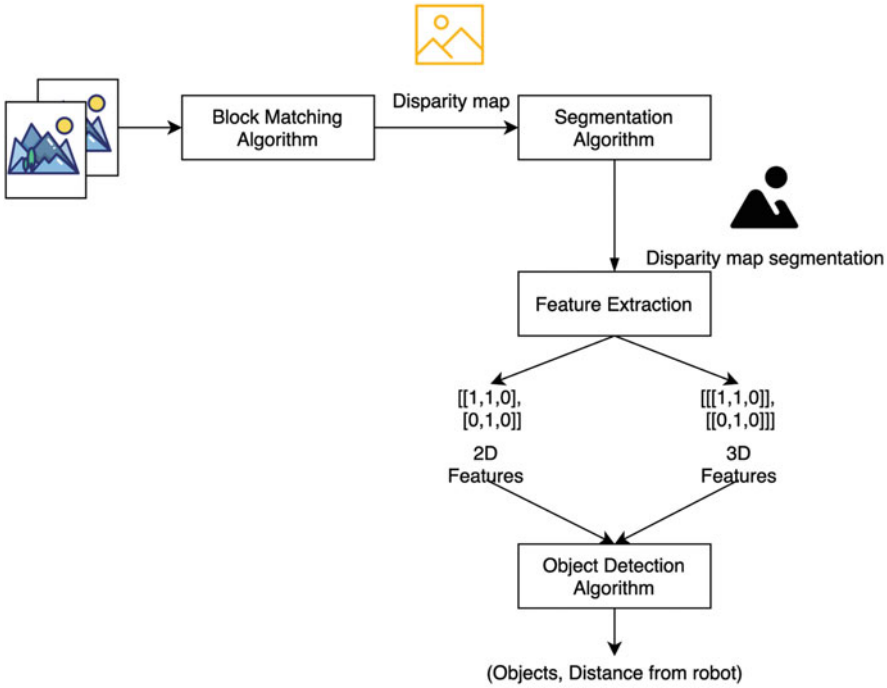
The decision module takes the information from sensors, including object information and distance from the robot, to decide which action to do next. The reinforcement learning model can be used to implement the decision module (Sutton and Barto 2018).

Robot Control Module

The robot control module controls the robot's hardware to perform the action given by the decision module. Note that the robot can contain more than one control module for various purposes (Brooks 1986). The list of control modules essential for healthcare robots are as follows:



Locomotion and Human Tracking in Healthcare Robots, Fig. 1 System architecture



Locomotion and Human Tracking in Healthcare Robots, Fig. 2 Vision module process

L

1. Cruiser module (Basu and Redi 2004)
   This module controls the robot's movement. It decides the voltage level that will be fed to the motors to control the speed and the direction.
2. Linear motion module for robot hand movement (Catalano et al. 2012)
   This module controls the simple action of the robot's arms, which are up, down, left, and right.
3. Rotation motion module for robot hand movement (Osswald and Wörn 2001)
   This module controls the complex movement of the robot's arms, which are grabbing and rotating the wrists.

Furthermore, the control modules need to be dynamic, robust, stable, and responsive since the environment varies from time to time. Finally, it should be fast enough to interact within a suitable time.

Definitions

Locomotion in a virtual reality video game is the travel in virtual world in order to move to a desired location.

Introduction

Most of the virtual reality (VR) systems, including virtual reality video games, often require harmoniously designed components such as audio and visual elements, task design, virtual worlds, as well as interaction and locomotion techniques. Locomotion is among the most important and very commonly used tasks in 3D virtual reality games (Bowman et al. 2004). Small position and rotation changes of the virtual viewpoint can be performed by head movements in immersive virtual reality systems that have head tracking capabilities. Such systems often use head-mounted displays to present the virtual world to the player. However, if the game requires a larger amount of travel than the real-world area, then a different locomotion technique needs to be used.

Recently in the late 2010s, many new generation, head-mounted displays became available, which are characterized as being highly immersive and affordable. HTC Vive, Oculus Rift, and Sony PlayStation VR are among the most prevalent ones of these new generation head-mounted displays. Nowadays, gamers can also use their high-end smart phones as displays for Samsung Gear VR and Google Daydream VR headsets. Although immersive virtual environments that use head-mounted displays are usually suitable for being explored on foot, there is a common major limitation of these systems. They either cannot track the position of the user's head or the position tracking is limited to a small area. One approach can be designing the virtual environment not larger than the tracked physical area and implementing a 1:1 mapping for the virtual position of the player, based on the real-world position of the user. Although there are some well-known VR game examples that use this technique, such as the game titled "Job Simulator"; this is a significantly major

limitation for game design. For VR games or applications with larger virtual environments, this 1:1 mapping technique would not work, since users will eventually go outside the real tracking space. To overcome this problem, several different locomotion techniques have been proposed in the literature. This entry reviews VR locomotion techniques that have been widely researched or used in commercial VR systems.

Virtual Reality Locomotion Techniques

Algorithm-Based Techniques

These locomotion techniques are constructed on algorithms without depending on any specific hardware. This category includes real walking (redirected walking) and gesture-based locomotion techniques (walking-in-place and flying/leaning).

Real Walking

Although it is shown to be the most presence-enhancing (Usoh et al. 1999) and less cognitively demanding (Marsh et al. 2013; Ruddle et al. 2011) locomotion technique, the real walking technique has the physical limitation of the tracking area (Whitton et al. 2005), which can make it impossible to utilize in small-sized physical spaces. In order to work around this limitation, redirected walking was introduced. Redirection can be described as altering the visual cues in virtual reality to keep the users inside the tracked area (Razzaque et al. 2001). This technique makes it possible to map large virtual environments to smaller tracked areas. In this technique, gains are applied to the locomotion data to alter user's visual cues. Keeping these gain values within the unnoticeable range is critical in order not to break user's immersion. The range for unnoticeable gain values were reported as follows: Translation −14% and 26%; Rotation −20% and 49%; and Curvature Radius 22 m (Steinicke et al. 2008, 2009, 2010). Although the virtual viewpoint of the user is altered, they can still reach to the edge of the physical tracked area. For such cases, accompanying methods were developed such as "Freeze Backup," "Freeze-Turn," "2:1-Turn" (Williams et al. 2007), and "virtual distracters" (Kohli et al. 2005; Peck et al. 2010). The aim of these accompanying methods is to make the user walk towards the center of the tracked area.

Another approach that aimed to enable real walking in virtual environments was known as "environment change." In this approach, the virtual environment's architecture was changed according to the user's navigation. In one technique, orientation of virtual doors was changed (Suma et al. 2011). In another technique, self-overlapping virtual spaces were used, which were referred to as "impossible spaces" (Suma et al. 2012) and "flexible spaces" (Vasylevska et al. 2013). In parallel lines, some portal door techniques emerged to minimize the need for real walking: "Arch-Explore" (Bruder et al. 2009) and barrier tape (Freitag et al. 2014).

Gesture-Based Techniques

These techniques aim to utilize body gestures, instead of making users really walk. Walking-in-place, flying, and leaning are among the most commonly used ones. In walking-in-place, users perform marching gesture but do not actually move in any direction in real-world (Slater et al. 1995a, b). Important attributes of walking-in-place method are as follows: step detection gesture (Feasel et al. 2008; Nilsson et al. 2013a, b; Templeman et al. 1999; Terziman et al. 2010; Wendt et al. 2010); step detection device (Feasel et al. 2008; Kim et al. 2012; Wendt et al. 2010; Williams et al. 2011; Zielinski et al. 2011); start and stop latency (Feasel et al. 2008); smooth speed control (Whitton and Peck 2013); visual gain range, which was reported as 1.65–2.44 (Nilsson et al. 2014).

Another gesture-based locomotion technique which have been commonly used in VR is flying (Guy et al. 2015; Robinett and Holloway 1992; Ware and Osborne 1990). In this flying method, user automatically moves the virtual view through some gestures. This technique offers easy implementation and ease of use; however, it was reported to be less realistic and less presence-enhancing as compared to other locomotion techniques (Usoh et al. 1999). The main issues

associated with flying were low degree of control in speed and low resemblance to real life walking interaction. A similar locomotion technique is leaning, in which users utilize their torso to control speed and rotation of locomotion. Different methods or tools have been utilized for detecting shifts in body weight such as "Nintendo Wii Balance Board" (Valkov et al. 2010) and "Human Joystick" (Harris et al. 2014). Leaning method was reported to provide higher degree of control; however, it requires more balance and body control skills. A recently popularized VR locomotion technique is referred as "Point and Teleport" that enables users to point to a place and instantly get teleported there (Bozgeyikli et al. 2016).

Tool-Based Techniques

These locomotion techniques rely on tools that give accurate position and rotation data. These tools can be stationary (walkers and standard controllers) or mobile (wearables and robots).

Stationary Tools

Stationary tools are fixed to a surface, which is usually the ground, and users climb on them for locomotion. They can work with physical effort exerted by user or through a triggering method. Physical exercise tools such as treadmills and stationary bicycles have been used for VR locomotion (Brooks 1987). In this approach, user wears a head-mounted display and uses these tools for moving in the virtual world. In the recent years, several different treadmills have been utilized for VR locomotion: unicycle; unidirectional and omnidirectional treadmills (Darken et al. 1997; Iwata 1999a, b); torus design-based treadmill (Schwaiger et al. 2007; Souman et al. 2008); low-friction surface (Jiung-Yao 2003; Suryajaya et al. 2009), ball bearings and belt combination referred to as "CyberCarpet" (De Luca et al. 2013).

Another type of stationary locomotion tools is standard controllers. Among the most commonly used ones are joysticks, joypads, and keyboards. It was reported that standard controllers are the most prevalent VR locomotion devices (Darken and Sibert 1996; Zhixin and Lindeman 2015). Main advantages are affordability in terms of price, simplicity, and familiarity from real-life experiences. Some studies resulted in findings of joystick providing better user experience in terms of locomotion as compared to other techniques (Cirio et al. 2009; Nabiyouni et al. 2015), whereas other studies reported findings that indicate joystick provided worse user experience in terms of locomotion (Peck et al. 2011, 2012; Riecke et al. 2010; Ruddle and Lessels 2006; Whitton et al. 2005).

Mobile Tools

Mobile tools are those that can be worn on user's body or moved around. Due to their complex nature, these tools are not widely available for typical consumers; however, these have been utilized in some experimental studies. For virtual reality locomotion, wearable tools such as "Cyber Boots" that included pressure foot sensors (Insook and Ricci 1997); "Waraji" that included a sandal with rotary sensors (Barrera et al. 2004); a shoe with six pressure sensors (Matthies et al. 2013); and "Powered Shoes" that included roller skates (Iwata et al. 2006) are used. In an experimental study referred to as "CirculaFloor," mobile robots were utilized as locomotion tools on which users could freely walk while not actually moving in any direction in the real-world (Iwata et al. 2005). As a drawback, all of these mobile tools require body-movement coordination and balancing skills from user's end.

Conclusion

Locomotion is an important part of virtual reality systems that may affect many factors related to user experience. Although there are several locomotion techniques that have been widely used in VR, each has its limitations or drawbacks. There is still need for exploration and improvement in this area. The introduction of the new generation VR devices in late 2010s can make it easier to explore locomotion and make it possible to introduce new locomotion ideas.

Blind bags; Blind boxes; Booster packs; Gachas; Gatchas; Loot crates; Prize crates; Random reward mechanisms; Randomized monetization methods; Surprise mechanics; Virtual Gashapons

Definition

Loot boxes are mechanics often found in video games that provide the player with randomized virtual rewards. Some loot boxes can be paid for with real-world money and therefore share structural and psychological similarities with gambling.

Introduction

"Loot boxes" is a colloquial catch-all terminology used to describe software features, typically found in video games, that provide the player with randomized virtual rewards (Drummond and Sauer 2018). The player must satisfy an "eligibility condition" to engage with (or "open") the loot box: This could be by defeating a certain in-game enemy, by obtaining a certain virtual item, by watching embedded commercials, or (more importantly) through purchasing using fiat currency (or real-world money) (Nielsen and Grabarczyk 2019). Once the player engages with the loot box, a "random procedure," of potentially varying degrees of complexity (Ballou et al. 2020), is used to determine what virtual rewards the player will obtain. The virtual "rewards" that the player obtains may be merely cosmetic items that, e.g., change the color of the player's armor, or may, alternatively, influence gameplay more significantly by, e.g., unlocking additional game content or increasing the player's in-game power (Xiao 2021). These "rewards" may be transferable (or "sold") to other players, in exchange for real-world money (Drummond et al. 2020b), or may be restricted by the video game company for use only inside the in-game economy by the original player who engaged with the loot box (Xiao 2020a). The act of engaging with a loot box may be represented in-game as the player literally opening a box containing loot; however, the loot box mechanic can also be visually represented in other forms, e.g., as tearing open a card pack, spinning a prize wheel, or receiving a capsule from a "gacha"

Loot Boxes: Gambling-Like Mechanics in Video Games, Table 1 Four categories of loot boxes proposed by Nielsen and Grabarczyk (2019)

Category	Description	Regulatory positions
Embedded-Embedded	**Costs** real-world money to engage, and its reward **does** have real-world value	**Regulated** as gambling in Belgium (Belgische Kansspelcommissie [Belgian Gaming Commission] 2018), the Netherlands (Kansspelautoriteit [The Netherlands Gambling Authority] 2018), the UK (UK Gambling Commission 2017), and most other countries that regulate gambling as a licensable activity **Banned** as gambling in most countries that more heavily prohibit gambling
Embedded-Isolated	**Costs** real-world money to engage, but its reward **does not** have real-world value	**Regulated** as gambling in Belgium (Belgische Kansspelcommissie [Belgian Gaming Commission] 2018) **Unregulated** in most other countries
Isolated-Embedded	**Does not** cost real-world money to engage, but its reward **does** have real-world value	**Unregulated** in most countries
Isolated-Isolated	**Does not** cost real-world money to engage, and its reward **does not** have real-world value	**Unregulated** in most countries

vending machine. Regardless of their visual representation, all loot boxes share the structural characteristics of being triggered by satisfying an "eligibility condition," involve a "random procedure," and provide "rewards," as described above.

Nielsen and Grabarczyk (2019) proposed a framework for classifying various implementations of loot boxes into four categories which focuses on whether the "eligibility condition" requires spending real-world money to satisfy, and whether the "rewards" can be transferred to other players in exchange for legal tender, and therefore possesses real-world value, as shown in Table 1.

Paid Loot Boxes in Context

Loot boxes that players have to purchase with real-world money to engage with are implemented by companies as monetization methods in video games, known as "microtransactions," which represent an alternative, or complementary, business model to selling copies of the software or providing subscription-based services (Petrovskaya and Zendle 2020). Analysis of loot box-spending data has revealed that the loot boxes of one single game (*Counter-Strike: Global Offensive*) generated US$528,000 in 1 day in one country alone, thus hinting at the immense size of the global loot box market (Zendle et al. 2020b).

In terms of the historical context and development of loot boxes, it has been suggested that using loot boxes to monetize video games was inspired by how collectible sports cards and fantasy trading cards (e.g., *Magic: The Gathering*) are sold in blind, randomized packs in order to encourage players to buy more packs and increase revenue (Nielsen and Grabarczyk 2019; Švelch 2020; Xiao 2021). These randomized packs were designed to contain rare cards, known as "chase cards," that were less likely to be included in packs than other cards and were therefore more sought-after and monetarily valuable. The consumer was thereby encouraged to purchase more packs in order to obtain such rare "chase cards," but they would more often only obtain less valuable, duplicate cards that they already possessed when they try to "chase" rare cards.

Loot boxes are implemented in highly popular home console games, e.g., the Ultimate Team Packs in Electronic Art's *FIFA* games (Electronic Arts 2019). Presently, loot boxes are prevalent in video games, particularly on mobile platforms,

e.g., Android and iOS: In 2019, 59% of the highest-grossing iPhone games in the UK contained loot boxes, while 36% of the 50 Highest grossing PC games on Steam contained loot boxes (Zendle et al. 2020a). Compared to in the UK, which represents the Western video game market, loot boxes are significantly more prevalent in China: In 2020, 91% of the 100 highest-grossing iPhone games contained loot boxes (Xiao et al. 2021b). This reflects that video game markets in different countries may implement loot boxes to different degrees. Video games containing loot boxes are also generally given low age ratings: 95% of the highest-grossing iPhone games containing loot boxes were deemed suitable for children aged 12+ (Zendle et al. 2020a). This suggests that children are regularly exposed to loot boxes and can readily purchase them. The UK Gambling Commission's survey (2019) found that 23% of 11- to 16-year-olds reported paying real-world money for loot boxes.

Potential Harms: Links with Problem Gambling

Paid loot boxes, because of the fact that players spend real-world money to engage with them and because of their randomized nature, are structurally and psychologically similar to gambling (Drummond and Sauer 2018). This encompasses Embedded-Embedded and Embedded-Isolated loot boxes under Nielsen and Grabarczyk's categorization (2019). Further, loot box purchasing has been found to be positively correlated with problem gambling severity in more than a dozen empirical studies in Western countries (Garea et al. 2021), e.g., the USA (Zendle and Cairns 2019), Australasia (Drummond et al. 2020a), Denmark (Kristiansen and Severin 2019), and Germany (von Meduna et al. 2020). Players with higher problem gambling severity tend to spend more money purchasing loot boxes (Zendle and Cairns 2018). In Western countries, loot box spending appears to be more strongly correlated with relatively "gamified" gambling games, e.g., online slot machines, and not correlated with more traditional gambling formats, e.g., playing bingo or the lottery in person (Zendle 2020). The relationship between loot boxes and gambling may be weaker in non-Western countries where gambling is more heavily prohibited, rather than regulated as a licensable activity, e.g., China, where lottery products represent the only legally available commercial gambling opportunity (Xiao et al. 2021a). Cultural differences and legal differences in gambling product availability may affect the relationship between loot boxes and gambling and remain a direction for future research.

Further, as in gambling contexts (Deng et al. 2021; Muggleton et al. 2021), the vast majority of loot box revenue is generated by a small minority of players spending significant amounts of money (Zendle et al. 2020b). This small minority of players have been identified as generally being players with problem gambling issues, rather than players with high personal incomes, thus suggesting that video game companies may be disproportionally profiting from potentially vulnerable consumers (Close et al. 2021). Researchers have also suggested that cognitive biases that are present in gambling contexts, e.g., the gambler's fallacy and loss chasing, which lead to maladaptive gambling, may also apply to loot box purchasing behavior and lead to maladaptive loot box overspending (King and Delfabbro 2018; Nielsen and Grabarczyk 2019; Xiao 2021). Finally, it has yet to be determined whether engagement with loot boxes in childhood affects a person's risk of developing gambling problems later in life.

Regulation by Law and Industry Self-Regulation

Paid loot boxes have been the subject of regulatory scrutiny by gambling regulators and policymakers in many countries because of their similarities with gambling and because of the link between loot box purchasing and problem gambling severity (Cerulli-Harms et al. 2020). In

particular, concerns about children engaging with loot boxes have been raised because they may be more susceptible to overspending money and more in need of consumer protection measures (Wardle and Zendle 2021; Zendle et al. 2019). Different jurisdictions are regulating the various categories of loot boxes to varying extents (Xiao 2021), as shown in Table 1. Applying existing gambling law has been how loot boxes have become regulated in nearly all countries: Various countries diverge as to which of the two categories of paid loot boxes (i.e., Embedded-Embedded and Embedded-Isolated loot boxes as defined by Nielsen and Grabarczyk) constitutes gambling and is therefore regulated: Nearly all countries agree that Embedded-Embedded loot boxes constitute gambling, but only a small minority of countries (e.g., Belgium) have taken the position that Embedded-Isolated loot boxes also constitute gambling. It is rather paradoxical that randomized physical sports and trading card packs, which arguably inspired loot boxes, are generally not considered to be a form of gambling and have thereby evaded regulatory scrutiny. Such physical packs legally constitute gambling in most countries because: They are bought with real-world money; their content is randomized; and the content has real-world monetary value because it can be sold to other people. Future research should consider why such physical Embedded-Embedded loot boxes are not considered to be gambling (Zendle et al. 2021).

The simplest regulatory solution is to ban the sale of loot boxes. This has effectively been done in Belgium where all paid loot boxes have been determined to be gambling and where no gambling licenses have been granted to video game companies for the sale of loot boxes (Belgische Kansspelcommissie [Belgian Gaming Commission] 2018). This prevents Belgian players from purchasing loot boxes and thus shields them from potential harms. However, this ban in Belgium has led to the removal of many video games that rely on loot boxes to generate revenue and which can no longer be profitably operated in that country (Xiao 2021). A blanket ban does not offer players freedom to play the video games they want or to engage with loot boxes and negatively affects video game companies' commercial interests. Conversely, nonregulation would continue to expose players, including vulnerable consumers, to potential loot box harms, and is arguably inadequate and unsatisfactory because of the precautionary principle of public health (Digital, Culture, Media and Sport Committee of the House of Commons (UK) 2019), which states that the lack of scientific certainty cannot justify regulatory inaction in a situation of high potential risk. Middle ground approaches that lie between a blanket ban and nonregulation have also been proposed and adopted in certain countries, e.g., restricting loot box purchasing only when a player attempts to go above a certain maximum spending limit (Drummond et al. 2019; Xiao 2020b, 2021).

Other consumer protection measures, which have been applied in gambling contexts (Livingstone et al. 2019), have also been identified as being potentially applicable to loot boxes (King and Delfabbro 2019; Xiao and Henderson 2021). The most prominent nonrestrictive regulatory measure is the disclosure of "winning" probabilities, which reveals how likely a player is to obtain a particular reward, as implemented in *Mario Kart Tour* (2019). This would require video game companies to reveal and publish the exact probabilities of obtaining each randomized loot box reward. The video game industry has increasingly imposed this requirement as self-regulation, e.g., by Apple (Kuchera 2017), Google (Gach 2019), and the major hardware providers and game publishers (Entertainment Software Association (ESA) 2019). This measure has also been adopted as law in China (presently the only country to do so), which has led to widespread compliance; however, the prominence and accessibility of disclosure have been identified as being suboptimal (Xiao et al. 2021b). A survey of Chinese video game players found that 85% of loot box purchasers reported seeing probability disclosures (meaning that they have been reasonably widely seen by players); however, only 19% of this group reported spending less money on loot boxes as a result of seeing the disclosures (Xiao et al. 2021a). This suggests that loot box probability disclosures may be of limited effectiveness at reducing loot box spending even if

they are accessibly and prominently displayed such that all players can see them (Xiao and Newall 2021). The video game industry has been widely supportive of loot box probability disclosure as an industry self-regulatory measure aimed at ensuring consumer protection (Entertainment Software Association (ESA) 2019), but whether self-regulation is effective remains to be assessed by future research.

Loot boxes and gambling may share many structural similarities; however, they are dissimilar in at least one regard: how the company makes money. Gambling operators lose money when the player wins money, which is why gambling operators must ensure that the gambling games are designed such that the operator is more likely than the player to win. In contrast, a video game company does not directly lose money when the player wins a reward, valuable or otherwise, as it does not directly cost money to give players these virtual rewards. However, it should also be noted that a video game company would face an indirect loss when a player wins a valuable reward (Xiao 2020c): A player may stop purchasing a loot box after receiving their desired reward, meaning that the video game company may stop making money from that player after the valuable reward is given out. In order to be sustainable, many loot box systems rely on frequent updates with new rewards, but each new reward costs money for the video game company to develop, meaning that companies would have to expend more costs to develop more new content if players are able to more easily obtain desirable rewards. Further, the value and desirability of a reward would decrease if all players managed to obtain it: It would no longer be a "rare" reward with which players could impress others. However, despite the potential for indirect loss, video game companies are still financially able to give out their most valuable rewards more frequently than traditional gambling operators. This means that loot box consumer protection methods do not have to be limited to what has been done in gambling contexts, and that loot box consumers could be additionally protected by novel features of ethical game design, e.g., allowing players to win valuable rewards more often (King and Delfabbro 2019; Xiao and Henderson 2021; Xiao and Newall 2021).

Conclusion: Directions for Future Research

Loot boxes, and paid loot boxes in particular, represent a relatively novel mechanic in video games. Despite increasing research attention being paid to the issue, further research is required to fill in the existing knowledge gaps. Future correlational research between loot boxes and gambling should examine whether loot box purchasing is more strongly correlated with engagement with specific gambling products, rather than engagement with gambling in general. Existing research has largely utilized self-reported data: Transparent collaboration with the video game industry may provide more reliable data. Indeed, qualitative methods may assist in better understanding individual players' experiences with loot boxes (Nicklin et al. 2021), and gauging players' views as to the implementation and regulation of loot boxes (Petrovskaya and Zendle 2021): This is especially relevant for Embedded-Isolated loot boxes because, although this category represents the vast majority of paid loot boxes implemented in video games, these mechanics have no obvious counterparts in nondigital contexts, and therefore there is no translatable literature from other fields. Further, cross-cultural perspectives would clarify whether players in various countries are experiencing loot boxes differently. Additionally, neuroscience perspectives may shed light on how player's cognition is affected when engaging with loot boxes: Such perspectives are prominent in research on gambling disorder; however, as of yet, they are missing from the loot box literature. Finally, the prevalence of serious problems with loot box spending has never been assessed, and it is not known whether such problems are caused by exposure to loot boxes or are instead symptoms of preexisting underlying issues. In conclusion, despite recent advances made by the literature, loot boxes remain an area deserving of further research.

Ludii General Game System for Modeling, Analyzing, and Designing Board Games

Cameron Browne, Éric Piette, Matthew Stephenson and Dennis J. N. J. Soemers
Maastricht University, Maastricht, Netherlands

Definition

The Ludii computer program is a complete general game system for digitally modeling, analyzing, and designing a wide range of games. These include traditional tabletop games such as board games and dice games, in addition to card games, graph games, mathematical games, puzzles, simulations, and simple video games. Ludii supports stochastic (chance) elements, hidden information, adversarial and cooperative modes of play, and any number of players from 1 to 16.

The system differs from existing *general game playing* (GGP) programs in a number of ways. Its underlying ludemic model allows a wider range of games to be described more easily and succinctly than other approaches, and it is intended as a tool for game *design* as much as game *playing*. Ludii belongs the "hybrid" class of GGP approaches that allows extensible higher-level game descriptions (Kowalksi et al. 2020).

The Ludii distribution comes with over 1000 predefined games and a number of default *artificial intelligence* (AI) agents for playing and analyzing these, in addition to new games authored by users. An open Ludii AI API is provided to facilitate the system's use as a platform for general game-based AI research. Ludii's Java code base is freely available under a Creative Commons (CC BY-NC-ND 4.0) license.

Ludii was developed as part of the European Research Council (ERC) funded Digital Ludeme Project with one of its primary purposes being for the reconstruction of historical games from partial rulesets based upon the available evidence (Browne et al. 2019b). However, this is only one application, and Ludii provides a range of features intended to help the modern game designer prototype, fine tune, and discover new designs.

The Ludii System

The Ludii system is based on the notion of the *ludeme*, which can be described as a game related concept or element of play that is relevant to the equipment and/or rules of a game (Browne 2021). Ludemes constitute the fundamental building blocks of which games are composed.

Games are defined for Ludii as structured ludeme trees in the form of LISP-like symbolic expressions, according to a custom grammar that constitutes the *Ludii Game Description Language* (L-GDL). For example, the game Tic-Tac-Toe can be defined as follows:

```
(game "Tic-Tac-Toe"
   (players 2)
   (equipment {
      (board (square 3))
      (piece "Disc" Each)
   })
   (rules
      (play (move Add (to (sites
      Empty))))
      (end
         (if
             (if Line 3)
             (result Mover Win)
         )
      )
   )
)
```

This *ludemic model* for describing games allows a wide range of games to be described simply and succinctly. The fact that ludemes encapsulate key game concepts makes such descriptions highly conducive to automated manipulations such as the evolution of new games from existing rulesets (Browne 2009).

Architecture

Figure 1 shows an overview of the main components of the Ludii system. Additional information on the relevant modules are provided in the following sections.

The game description (written using the L-GDL) is initially passed into the Grammar module, which first expands and parses the game description to check that it is syntactically valid. Once this initial check is done, the game description is then compiled, transforming it into its internal logic format within the Core module. This internal logic contains all the relevant information about the game, including the equipment, rules, and supplementary metadata. The metadata provides additional information about the game which is not related to how it is played. This includes textual information about the game – such as its rules, author, and historical details – but also graphical information about how the game should be visualized.

The rules section of the Core module is then used by the Manager module, which is responsible for coordinating the moves of the game. This module takes input from either a human user, via the Player module, or an Agent, via the AI module.

The equipment section of the Core module is used by the ViewController module, which is responsible for constructing the relevant graphics for the containers and components used in the game (view) as well as how interface inputs should be converted into game moves (controller). Any graphical options specified in metadata are also used by the view section of the ViewController module, to supplement or override what is defined in the equipment. For example, a metadata line could be added to the game that changes the size of a piece or the color of the board.

The Player module displays the visuals provided by the ViewController module to the user. When the user interacts with these visuals, the controller converts these inputs into a logical move and sends this to the Manager module. The Player module provides different visuals and interaction handling depending on if the user is operating on their own local version of Ludii (desktop) or the remote website version (web). Once the Manager module verifies that this move is valid, it is passed to the Core module, where the state of the game is updated.

Grammar

The custom Ludii Grammar is an Extended Backus-Naur Form (EBNF) style grammar consisting of a set of production rules used to generate game descriptions. The grammar is generated automatically from the Ludii code base using a *class grammar approach* in which all keywords, rules, and instantiations are derived directly from their corresponding Java classes (Browne 2016).

This approach provides a 1:1 correspondence between the L-GDL and the underlying Java code at all times, effectively making the Ludii Grammar a snapshot of the current class hierarchy and making the system easily extensible. New functionality can be added by simply implementing the relevant Java classes, which will then be automatically incorporated into the grammar the next time that Ludii is launched.

Each game description is contained in a plain text file with *.lud extension. When a game description is loaded into the Ludii system, the following steps are performed to compile the description into an executable Game object, as shown in Fig. 1:

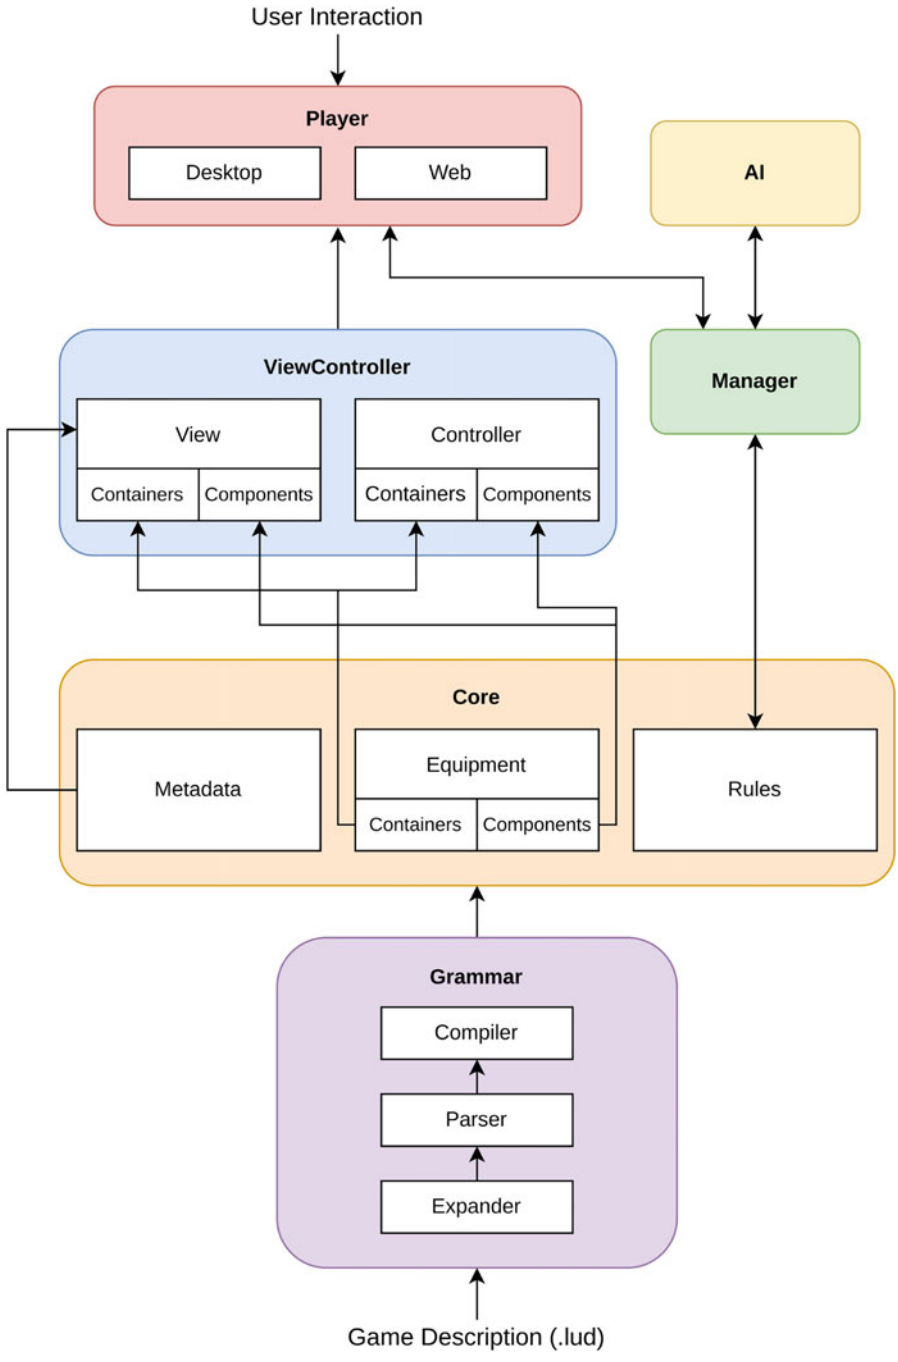
1. *Expand:* The game description is expanded into a plain text string to resolve certain metalanguage features and decorations.
2. *Parse:* The resulting string is parsed for correctness according to the current Ludii Grammar.
3. *Compile:* The Java classes corresponding to the game description keywords are recursively instantiated with the specified parameters to produce an executable Game object in Java bytecode.

Internal Model

The game representation and the transitions between states are described in the following sections.

Game Representation

A game is defined as a 4-tuple of ludemes:



Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Fig. 1 Architecture overview of the Ludii general game system

- **Players**: provides the information about the players (number of players, direction of each player, ...).
- **Mode**: corresponds to the game control and describes if the game is played alternatingly or simultaneously.

- **Equipment**: describes all the information about the containers used in the game (boards and hands) as well as the components (i.e., the game pieces).
- **Rules**: describes the initial state, how different components interact with each other, what moves can be made, and the conditions to reach a terminal state.

Figure 2 shows the components of a game in Ludii.

State Representation

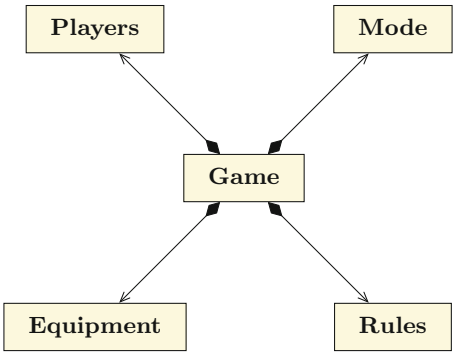
A Ludii game state s encodes which player is to move in s as well as which player was moving in the previous state and which player is going to move in the next state.

Each container of a game is modeled as a graph defined by a set of cells C, a set of vertices V, and a set of edges E. Each playable *location* $l = \langle c_i, t_i, s_i, l_i \rangle$ is specified by its container $c = \langle C, V, E \rangle$, a site type $t_i \geq$.

$\in$ {Cell, Vertex, Edge}, a site index $s_i \geq 0$, and a *level* $l_i \geq 0$. Every location specifies a type of site in a specific container at a specific level. Each container of the game has its state representation called container state.

A container state cs is implemented as a collection of data vectors for each playable site. The different data vectors are:

- what[l]: The index of the component at l, or 0 if there is no component.
- who[l]: The index of the owner of the component at l, or 0 if there is no component.
- count[l]: The number components (of a single type) at l.
- state[l]: The local state of the component at l, or 0 if there is no component.
- value[l]: The value of the component at l, or 0 if there is no component.
- rotation[l]: The rotation index of the component at l, or 0 if there is no component.



Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Fig. 2 The game components

Different representations are implemented to minimize the memory footprint and to optimize the time needed to access necessary data for reasoning on any game. These representations are:

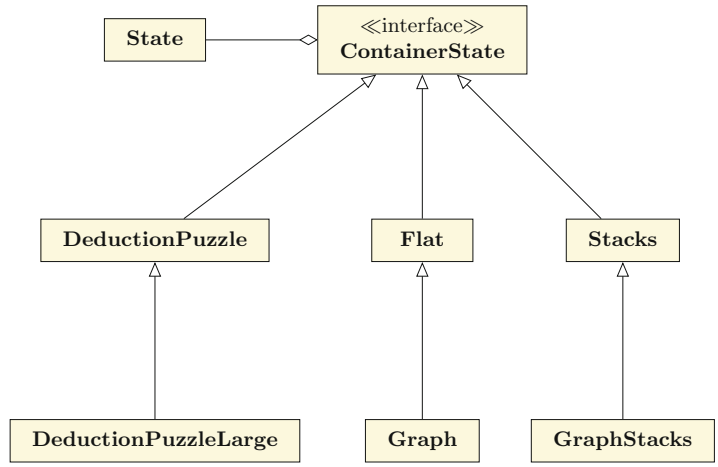
- Flat state: For games played on one single site type without stacking.
- Graph state: For games played on multiple site types without stacking.
- Stack state: For stacking games played on one single site type.
- Graph Stack state: For stacking games played on multiple site types.
- Deduction Puzzle state: For puzzles corresponding to a Constraint Satisfaction Problem (Piette et al. 2019).

Figure 3 shows the relations between the different state representations. Thanks to these different state representations, Ludii is able to model a very large set of various games. Figure 4 shows an overview of the Ludii games library (1019 games in version 1.3.0).

Trial and State Transitions

A Ludii successor function is given by $\mathcal{T}$: $(\mathcal{S} \backslash S_{\text{ter}}) \times \mathcal{A} \mapsto S$, where $\mathcal{S}$ 6is the set of all the Ludii game states, S_{ter} the set of all the terminal states, and A the set of all possible lists of actions, where a single list of actions is a move that a player can select. Given a current state $s \in \mathcal{S} \backslash S_{ter}$, and a list of atomic actions $A = [a_i] \in \mathcal{A}$, $\mathcal{T}$ computes a successor state $s' \in \mathcal{S}$.

A trial τ is a sequence of states s_i and action lists $A_i : s_0, A_1, s_1, \ldots, s_{f-1}, A_f, s_f$ such that $f \geq 0$, and for all $i \in \{1, \ldots, f\}$,



Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Fig. 3 The different state representations

Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Fig. 4 Some example visualizations of games from the Ludii Library

- The played action list A_i is legal for the mover (s_{i-1}).
- States are updated: $s_i = \mathcal{T}(s_{i-1}, A_i)$.
- Only s_f may be terminal: $\{s_0, \ldots, s_{f-1}\} \cap \mathcal{S}_{ter} = \emptyset$.

When a new state s_{i+1} is reached after applying A_i selected from the list of legal moves for a state s_i, Ludii computes the new list of legal moves of s_{i+1} and stores them in the trial for any caller to access them quickly without needing to compute them again.

A trial is over when all players are inactive and associated with a rank. The outcome of the game corresponds to the ranking of the players.

In short, a trial τ provides a complete record of a game played from start to end, including all the moves made stored in a list. Any reasoning on any

game can be parallelized using separate trials per thread. All the data members of a game are constant and can therefore be shared between threads. A thread will be able to use a trial τ to compute any playout from any state.

In Ludii, a single object called *Context* is used to store references to the game, the state representation s, and the trial τ. For any operation such as computing the graph of a container, computing the initial state s_0, or computing the legal moves for a state s, Ludii evaluates a tree of ludemes by calling a method eval(context) to evaluate it according to the current state. The *Context* also contains the random number generator used for any stochastic operations in the corresponding trial and the value of the model – alternating or simultaneous – used to apply moves or compute the legal moves in a specific game state. Alternating-move models expect only a single player to select a move at a time, whereas simultaneous-move models expect *all* active players to select a move at every time step, and simulations simply apply all legal moves automatically. More details about the internal model can be found in Piette et al. (2021).

Board Representation

In Ludii, the board shared by all players is represented internally as a finite graph defined by a triple of sets $\mathcal{G} = \langle V, E, C \rangle$ in which V is a set of *vertices*, E a set of *edges*, and C a set of *cells*.

For example, Fig. 5a shows a game with pieces played on the vertices, edges, and cells of the board graph. Figure 5b shows a board game played only on the cells but in which pieces may stack.

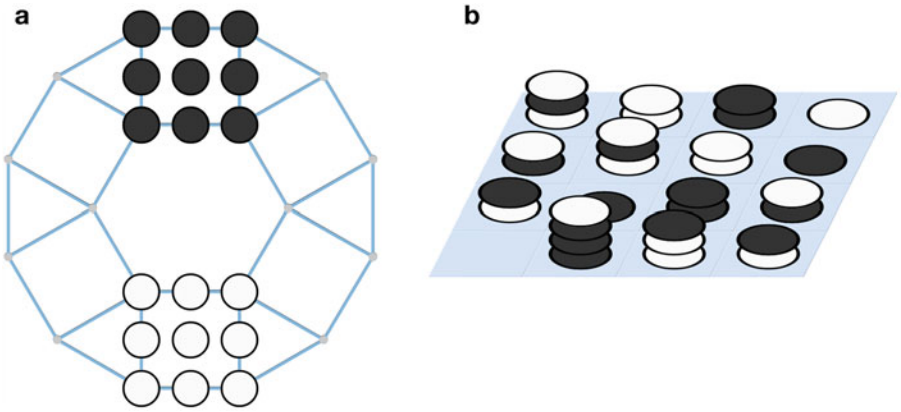
In any given game, a component (or a stack of components) can be placed on any location corresponding to a graph element and a level.

Two different graph elements can have different relations: Adjacent, Orthogonal, Diagonal, Off Diagonal, or All. The complete definition of each of these relations is provided in Browne et al. (2021). These relationships are summarized for the regular tilings in Table 1.

Ludii supports the following direction types:

- *Intercardinal* directions: `N`, `NNE`, `NE`, `ENE`, `E`, `ESE`, `SE`, `SSE`, `S`, `SSW`, `SW`, `WSW`, `W`, `WNW`, `NW`, and `NNW`.
- *Rotational* directions: `In`, `Out`, `CW` (clockwise), and `CCW` (counterclockwise).
- *Spatial* directions for 3D games: `D`, `DN`, `DNE`, `DE`, `DSE`, `DS`, `DSW`, `DW`, `DNW` and `U`, `UN`, `UNE`, `UE`, `USE`, `US`, `USW`, `UW`, and `UNW`.
- *Axial* directions subset (for convenience): `N`, `E`, `S`, and `W`.
- *Angled* directions subset (for convenience): `NE`, `SE`, `SW`, and `NW`.

Each graph element has a corresponding set of *absolute directions* and *relative*



Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Fig. 5 A game played on vertices, edges, and cells (**a**) and a game played only on cells (**b**)

Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Table 1 Relations for the regular tilings

Relation	Square	Triangular	Hexagonal
All			Adjacent			Orthogonal			Diagonal			Off-Diagonal			
directions to associated graph elements of the same type. Absolute directions can be any of the above direction types in addition to any relation type (`Adjacent`, `Orthogonal`, `Diagonal`, `Off Diagonal`, or `All`).

Relative directions from an element are defined by the direction in which a component is facing, the number of rightward steps of the component, and the graph relation to use at each step (Adjacent by default). Relative directions are: `Forward`, `Backward`, `Rightward`, `Leftward`, `FR`, `FRR`, `FRRR`, `FL`, `FLL`, `FLLL`, `BR`, `BRR`, `BRRR`, `BL`, `BLL`, or `BLLL`.

Game Logic

The logic of an L-GDL game (Piette et al. 2021) is computed from its *rules*, ludeme which is defined by the following ludemes which correspond to different rule types:

1. *meta*,
2. *start*,
3. *play*,
4. *end*.

For example, the following L-GDL code describes the Game of the Amazons (Amazons: ludii.games/details.php?keyword = Amazons) with an additional swap rule (a rule that allows the second player to swap colors after the first move to reduce any first move advantage). This game is used as example in the next sections.

```
(game "Amazons"
   (players 2)
   (equipment {
      (board (square 10))
      (piece "Queen" Each
       (move Slide (then (moveAgain)))
      )
      (piece "Dot" Neutral)
   })
   (rules
      (meta (swap))
      (start {
        (place "Queen1"
        {"A4" "D1" "G1" "J4"}
         )
        (place "Queen2"
          {"A7" "D10" "G10" "J7"}
        )
      })
      (play
        (if (is Even (count Moves))
          (forEach Piece)
          (move Shoot (piece "Dot0"))
        )
      )
      (end
        (if
          (no Moves Next)
          (result Mover Win)
        )
      )
   )
)
```

Metarules

In Ludii, a metarule, defined with the ludeme *meta*, is a global rule applied in each state s reached after applying the move decided by the player. That rule can modify the state s or can add/remove some moves from the list of legal moves. In the Game of the Amazons, the swap rule is defined using the metarule (*swap*) (line 12). Here, after the first player has finished their turn, the second player has one more legal move allowing them to swap with the other player. The metarules are optional.

Starting Rules and Initial State

When a game is creating after being compiled, the state s_{-1} corresponds to all the variables set to their default values and no piece placed in any playable location. The starting rules (lines 13–20) of the Game of the Amazons are used to place the queens on the expected locations to create the initial state. These rules define a list of movements A_0 applied to the state s_{-1} to build s_0. The starting rules are optional.

Playing Rules and Move Generation

The playing rules of a game describe how to generate the legal moves of the mover for any current state s_i. These legal moves are defined in the Play ludeme through its Moves ludemes. The playing rules of the Game of the Amazons are described in lines 21–26.

At each state s_i, the Moves ludeme used to describe the playing rules are evaluated according to the state and return a list of k legal moves $\mathcal{M} : \langle m_1, \ldots, m_i, \ldots, m_k \rangle$ stored in the trial τ. As described in Section, the transition between two successive states s_i and s_{i+1} is possible as a sequence of atomic actions A_i applied to s_i. Such a

sequence is modeled as a move $m : \langle a_1, \ldots, a_i, \ldots, a_n \rangle$, where n is the number of actions in A_i..

An atomic action a is the only operator able to modify the state after its creation. Consequently, when a player selects their move m from the list of legal moves available in the trial for the state s_i, this state is updated by applying successively each atomic action in the list of actions composing the move m.

Ending Rules and Terminal States

The ending rules describe when and how play can terminate for one or more of the players. In the Game of the Amazons, the ending rule (lines 27–32) checks whether the next player has no legal moves; if this is the case, the game is over and the current player wins.

In Ludii, any conditions to reach an ending state are described in the ending rules, followed by the description of the outcome of at least one player. In games with two players or fewer, an ending rule describes a terminal state s_{ter}, but for games with more players, the game can continue if play did not yet terminate for at least two of the players.

Functions

All the ludemes defining the rules are functions that are evaluated according to a state s returning a specific type of data. Five types of functions exist in Ludii:

- **Moves** functions return a list of moves. The Moves ludemes starting by (move ...) describes a decision move, all the other Moves ludemes are effect moves. To make the computation of the legal moves efficient, the effect moves which have to be applied before the decision action a_d are distinguished from those that have to be applied after, corresponding to the consequences of the decision and described using the ludeme (then ...). Due to that distinction, only the non-consequence moves are fully evaluated during the computation of the legal moves, and the consequences are evaluated only when a specific move has been selected to be applied by the player. In the context of the slide movement of the Game of Amazons, the effect Moves ludeme (moveAgain) is evaluated when a slide move is decided, setting the next player be the current mover.
- **Arithmetic** functions return one or many numerical values. The arithmetic functions are composed of many different functions according to the type of numerical values returned (array, integer, range, or real). As examples, the ludemes (count Sites "Board") and (count Players) return the number of sites in the board, and the number of players, respectively.
- **Logic** functions return a Boolean value. The most common logic functions start by (is ...), such as (is Even (count Moves)), which returns true if the number of moves played so far is even.
- **Region** functions return one or many playable sites. The most common region functions start by (sites ...), such as (sites Board), which returns a list of all the sites on the board.
- **Direction** functions return one or many absolute directions. For example, (directions {Rightward, Leftward}) is returning the absolute directions corresponding to the right and left of the current direction of a piece.

Ludii Player

The Ludii Player provides the graphical user interface (GUI) aspect of Ludii. This includes both the visuals and controls for playing games, as well as additional software options to improve the user/developer experience (e.g., remote online games, a built-in editor, game analysis tools, advanced graphical settings, etc.). This is something that is either missing or severely lacking in most other general game systems.

An example screenshot of the main Ludii Player GUI is shown in Fig. 1. This example demonstrates an in progress game of Shogi. The left side of the player shows the current state of the game board. The top right area of the player displays details about each player, including who is controlling them and the contents of their hand. The bottom right area provides supplementary information about the game, such as the moves that have been made, ludeme description, agent analysis results, etc. A range of menu options at

the top of the Ludii Player also provides many other alternative features.

A few of the user-friendly features offered by the Ludii Player, and their uses for research, are now described. Firstly, being able to visually see and play the games described using the L-GDL makes testing and verifying the correctness of game descriptions much easier. The benefit of this point should not be understated, as there have been several cases of games being described for alternative systems which were later found to be incorrect. Secondly, the heuristics and strategies of agents can be easily viewed to see their current performance and if there are any obvious weaknesses in their behavior. Humans can also play directly against agents to help determine if they are at a human-level playing strength. Lastly, providing a user-friendly interface is more inviting to the general public and encourages other game design enthusiasts to create their own games, leading to a larger range of games for research purposes. Ludii currently includes over 1000 games which were created by members of the general public, with new games being added frequently.

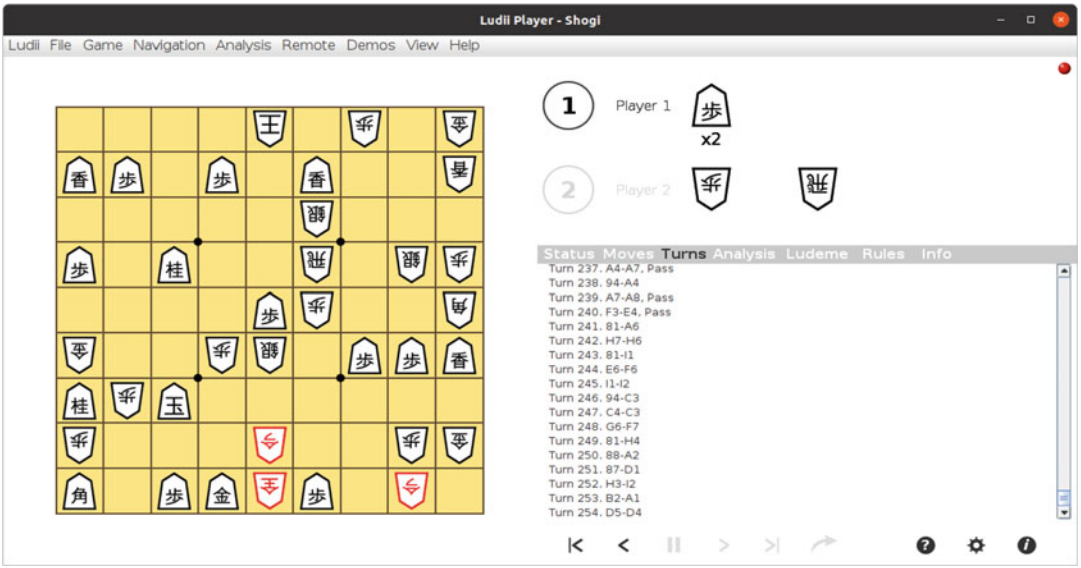
User Interface

The Ludii Player provides the graphical user interface (GUI) aspect of Ludii, including both the visuals and controls for playing games. There are currently two different version of the Ludii Player: the Desktop Player, which is used when running Ludii locally on any standard PC, and the Web Player, which is used when interacting via the Ludii Portal Website.

Ludii Desktop Player

An example screenshot of the Ludii Desktop Player GUI is shown in Fig. 6. The left side of the player shows the current state of the game board. The top right area of the player displays details about each player, including who is controlling them and the contents of their hand. The bottom right area provides supplementary information about the game, such as the moves that have been made, ludeme description, agent analysis results, etc. A range of menu options at the top of the Ludii Desktop Player also provides many other additional features, including but not limited to:

- The ability to play remote games and tournaments with other Ludii users online.



Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Fig. 6 The graphical user interface (GUI) of the Ludii Desktop Player for an in progress game of Shogi

- A built-in editor for creating, modifying, and saving Ludii game descriptions.
- Game analysis tools for evaluating and comparing games across a variety of metrics.
- Multiple graphical settings, such as animations, move highlighting, cell coordinates, etc.
- The ability to select different game options and rule sets.

Ludii Web Player

An example screenshot of the Ludii Web Player GUI is shown in Fig. 7. This picture was taken from a mobile smartphone device in portrait mode. Other devices may arrange certain elements such as the player hands differently, but are otherwise functionally identical. As can be seen, the Web Player contains less features that the Desktop Player, essentially only allowing the user to play the game against other AI or human opponents. The benefit of the web version, however, is that it can be played on almost any device with an internet connection and does not require the user to install Java beforehand.

Ludii Portal

Both the Ludii Web Player and the download link for the Ludii Desktop Player can be accessed via the Ludii Portal (ludii.games). This portal also provides additional information about Ludii and the games within it. Some of main web pages that can be accessed from this portal include:

- The Ludii Game Library (ludii.games/library), which displays images and category information for all games within Ludii. Selecting a game from this library will open a Web Player instance of that game.
- The Ludii Downloads Page (ludii.games/download), which contains links for downloading the Ludii Desktop Player, as well as other Ludii documentation.

Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Fig. 7 Ludii Web Player GUI for mobile devices, showing Chess

- The Game Concepts Search Page (ludii.games/searchConcepts), which can be used to search for games with a specific combination of over 700 defined concepts.
- The Ludeme Tree Page (ludii.games/ludemeTree), which displays an interactive hierarchy tree for all the ludemes within the L-GDL.

Artificial Intelligence

Ludii provides an API for game-playing agents using any artificial intelligence (AI) techniques to be developed and used to play any of Ludii's games from within its GUI-based player as well as command-line programs and competitions (Stephenson et al. 2019). The API for agents provides them with a *forward model*; given any (current) game state, this may be used to generate lists of legal moves, generate successor states resulting from the application of moves, query whether or not a game state is terminal or any rankings have already been determined, and so on. This is similar to the API provided by the General Video Game AI (GVGAI) framework (Perez-Liebana et al. 2019) for its collection of video games. This interface is sufficient for typical tree search algorithms as commonly used for GGP, such as Monte-Carlo Tree Search (MCTS) (Kocsis and Szepesvári 2006; Browne et al. 2012; Coulom 2007). There is also support for tensor representations of states and actions to be generated, the use of which has been demonstrated in a bridge between Ludii and the Polygames (Cazenave et al. 2020) framework of deep learning approaches for games. Various types of constraints can be specified for agents, such as processing time per move, maximum iteration count, and maximum search depth; different constraints may be more or less suitable for different experiments or use cases.

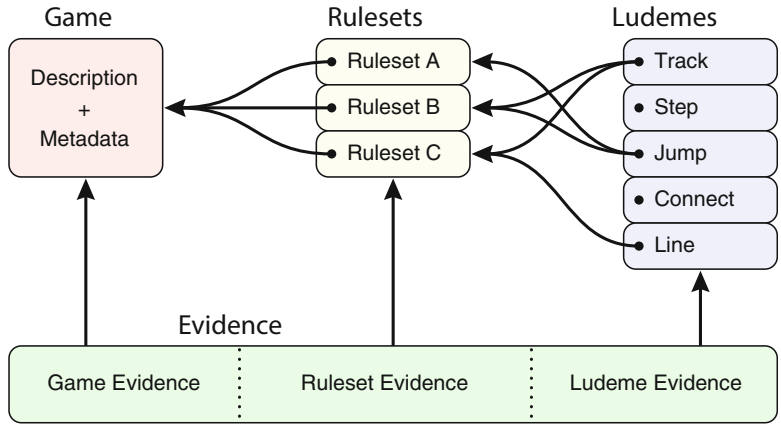
Based on this interface, several standard algorithms have already been implemented and included directly in Ludii, as well as new techniques developed and proposed specifically in the context of DLP and Ludii. In GGP, one of the most commonly used search algorithms is MCTS. Ludii includes implementations of several variants and common extensions, such as UCT (Browne et al. 2012), GRAVE (Cazenave 2015), MAST (Finnsson and Björnsson 2008), Progressive History (Nijssen and Winands 2011), and NST (Tak et al. 2012). It also includes training techniques and variants of MCTS that are guided by trained features, which are described in other publications (Browne et al. 2019a; Soemers et al. 2020).

Another search technique implemented in Ludii is $\alpha\beta$-search (Knuth and Moore 1975), with Max^N (Luckhardt and Irani 1986), Paranoid search (Sturtevant and Korf 2000), and BRS+ (Esser et al. 2014) extensions for games with more than two players. Unlike MCTS, these techniques require heuristic evaluation functions – generally based on domain knowledge – to compare the "desirability" of various states. A variety of heuristics, most of which were found to be fairly generally useful across multiple games (Browne 2009), are included in Ludii for this purpose. Typical examples include a *material* heuristic to count weighted sums of types of pieces owned by players or terms that compute proximity to board centers, corners, sides, and so on.

Ludii Database

All relevant information about each official Ludii game (i.e., those which are included within the code Ludii software and repository) is stored inside the Ludii Game Database (LGD). This data can be decomposed into two main types, *game-related* and *evidence-related*. The evidence-related data is primarily stored only for games that are relevant to the goals of the DLP. As such, a large portion of games in the LGD does not have any evidence-related information. As this information is unlikely to be useful outside of this archaeological context, this section will focus primarily on the game-related data. This game-related data can further be split into three subsections: *games*, *rulesets*, and *ludemes*. Each game can be thought of as being composed of one or more rulesets, with each rulesets being made up of multiple ludemes.

While the distinction between a game and a ruleset is not exact, two sets of rules/equipment can be considered different games if they come from different places or existed in different time



Ludii General Game System for Modeling, Analyzing, and Designing Board Games, Fig. 8 Overview of the main Ludii Game Database groups and their relationships

periods. If they cannot be separated, however, then they are considered different rulesets of the same base game. This can lead to two rulesets of the same game with very different rules/equipment, such as two different sets of rules that have been suggested for a historical game with largely unknown rules. It can also lead to two distinct games with very similar rules/equipment, to consider the possibility that these games were created independently in different places and times.

A rough outline of the LGD structure is shown in Fig. 8.

Games

Each game entry in the LGD describes a specific game (i.e., a single .lud game description) in Ludii. Each of these game entries will also have at least one ruleset associated with it, although it can have more. Auxiliary metadata information about each game is also stored, such as plain English descriptions of the game and its rules, any aliases, publication details, and so on.

Rulesets

A ruleset is a defined set of ludemes which describe the specific rules and equipment that is used to play a certain game. These rulesets could be speculative in nature or can simply be a known variant of an established game (e.g., the different scoring systems for the game Go). Playing the same game with a different ruleset can often lead to different gameplay experiences. One ruleset could make a game long and biased, with little room for strategic play while another could provide the complete opposite. As a result of this change, it is these rulesets that are evaluated and analyzed when it comes to gameplay, rather than the game itself.

Ludemes

A ludeme is single elemental building block of a game. Multiple ludemes can be combined together to create a description of a specific piece of equipment or rule that a game uses. Each ludeme is stored in the LGD and is associated with the rulesets which use it. If a game has any ruleset that uses a particular ludeme, then by extension, that game will also be considered as using that ludeme.

Definitions

Video game modding: It is the process of modification of a video game by players or fans, for changing the gaming experience by allowing others to get and use these modifications, which are referred to as "mods."

Ensemble learning: Use of multiple learning algorithms to obtain better performance than that obtained by using any of these algorithms in isolation

Transfer learning: It is the process of reusing knowledge from previously learned *source tasks* to bootstrap learning of target tasks (Braylan et al. 2016).

Introduction

There are multiple ways in which some or all of the research at the intersection of machine learning and computer games can be surveyed. One can survey the applications of one machine-learning paradigm in computer games in one genre. One can survey the applications of multiple machine-learning paradigms in computer games in one genre. One can survey the applications of one machine-learning paradigm in computer games from multiple genres. One can survey the applications of multiple machine-learning paradigms in computer games from multiple genres. Justesen

© Springer Nature Switzerland AG 2024
N. Lee (ed.), *Encyclopedia of Computer Graphics and Games*,
https://doi.org/10.1007/978-3-031-23161-2

and others have co-authored such a survey (Justesen et al. 2020). Machine-learning frameworks, representations, architectures, and algorithms covered in their survey include Deep Q-network (DQN), Distributional DQN, Deep recurrent Q-learning (DRQN), Hierarchical DQN (h-DQN), LSTM (long short-term memory) network, hierarchical deep reinforcement-learning network (H-DRLN), Neural Turing Machines (NTMs), recurrent memory Q-network (RMQN), feedback recurrent memory Q-network (FRMQN), teacher-student curriculum learning (TSCL) framework, Independent Q-learning (IQL), multiagent bidirectionally coordinated network (BiC-Net), convolutional neural-network-fitted Q-learning (CNNFQ), LSTM-DQN architecture, deep reinforcement relevance net (DRRN), deep distributed recurrent Q-network (DDRQN), Double DQN, dueling DQN, and Prioritized DQN. Q-learning is a reinforcement-learning algorithm.

One can survey genre-independent applications of one machine-learning paradigm in computer games. One can survey genre-independent applications of multiple machine-learning paradigms in computer games. A survey can also be driven by tasks related to computer games and machine learning. So one can survey uses of machine learning to solve tasks related to computer games. This chapter is a survey that covers some of the important applications of different machine-learning paradigms to computer games such that the methodology in these applications is either genre-independent or can be generalized to make it applicable to additional genres. This survey is organized by the abstract computer-game-related tasks addressed by one or more machine-learning paradigms.

Recognizing Genre Based on Audio

Amiriparian and others (2020) introduce game-audio-based genre recognition and present an approach to solve this problem. They extract the following three feature representations from game-audio files: knowledge-based acoustic features, DEEP SPECTRUM features, and quantized DEEP SPECTRUM features using Bag-of-Audio-Words. They considered recognition of the following six genres: Action or Shooter, Arcade or Platform, Fighting, Racing, Sports, and Simulation or World Building. They trained a linear SVM (support vector machine) classifier. They found that Racing games were the easiest to recognize due to automotive noises and Simulation and World Building games were the most difficult to recognize.

Game Balancing

A game is unbalanced when it is too easy or too hard for the human player. This imbalance can cause the player to lose interest in playing the game. According to Andrade and others (2005), dynamically balancing a game using reinforcement learning by giving a negative reward to the computer-controlled agent when the game is too easy or too hard is not a good solution to the game-balancing problem, as this solution can result in unbelievable behaviors like the computer-controlled agent not using defense at all after hitting the character controlled by the human player. Their challenge-sensitive action-selection mechanism requires the computer-controlled agent to periodically use the challenge function to evaluate if it is at the same level as the player. According to the challenge function proposed by them for a fighting game, whether the game is easy, moderately hard, or difficult, depends on the difference in the lives of the computer-controlled character and the human-controlled character. They used modified reinforcement learning. According to their approach, the computer-controlled agent progressively chooses sub-optimal actions if the game is too hard. Their modification to reinforcement learning resulted in the computer-controlled agent exhibiting win-loss balance.

Testing Hypotheses

Akbar and others (2021) used ensemble learning to test if inclusion of adult content allows a mod to

get more endorsements. The ensemble included recurrent neural networks (RNNs) and decision forest models. They found that adult content played an important role in determining the endorsement count of a mod.

Transferring Learning for Fulfilling New Tasks

Braylan and others (2016) propose GRUSM (General ReUse of Static Modules) for transfer learning. A GRUSM network is a 3-tuple G' = (M', S′, T') where M' is a traditional neural network (feedforward or recurrent) containing the new nodes and connections unique to the target task, with input and output nodes corresponding to inputs and outputs defined by the target domain; S′ is a (possibly empty) set of pointers to recruited source networks; and T' is a set of weighted transfer connections between nodes in M' and nodes in source networks (Braylan et al. 2016). Each source network can be a traditional neural network or a GRUSM network. Source networks are existing neural modules.

Improving Behavior Trees

A behavior tree represents behaviors at multiple levels of abstraction such that the behaviors at the lowest level are executable. Behavior trees can be used in computer games for controlling computer-controlled characters (non-playing characters). The root of a behavior tree for preys in (Dey and Child 2013) is the selector node. Its children are *Retreat*, *Idle*, and *Attack*. The children of *Retreat* are *Flee* and *SeekSafety*. The children of *Idle* are *Graze* and *Explore*. The children of *Graze* are *Forage* and *Eat*. The children of *Explore* are *Flock* and *Wander*. The children of *Attack* are *Charge* and *Assist*. *Assist* means attacking the nearest predator agent targeting a neighboring prey agent. The main goal in (Dey and Child 2013) is development of an approach for suggesting changes to a behavior tree, to assist game designers. Q-learning is used in (Dey and Child 2013). Their approach prioritizes the behaviors in a behavior tree based on their utilities.

Behavior Cloning

Since playing against superhuman opponents can be frustrating to human players, Diels and Kazmi (2021) propose cloning behavior of human players to create realistic opponents. They evaluate a behavioral clone of a game-playing agent by comparing action distributions and by comparing play-style data. They tried to clone a reinforcement-learning agent that was not allowed to improve after the training phase, a random agent sampling actions uniformly, and a human player. They show that cloning the behavior of a human player is more difficult than cloning the behavior of other agents since humans play least consistently.

Learning from Visual Game Display

NPCs (non-playing characters) are broadly defined as visible components of a game that are under the control of the computer, and that either work with or against the human player (Fink et al. 2007). Fink and others use machine learning to learn the behavior of NPCs from just the graphical output of the game generated during game play. They claim that this can be useful for knowing what the human player may learn during game play. The learnt behavior can be compared with the implemented behavior to know how well the human player can learn the implemented behavior. They claim that their method can be used to re-engineer the game if game code is not available. They use a similarity function and nearest-neighbor rule.

Personalizing Challenges

The framework (Georgiou and Demiris 2016) for altering the segments of a racing track according to model of the user uses linear regression for

finding weights of physiological and non-physiological metrics. Physiological metrics include metrics based on eye tracking and head pose. Non-physiological metrics include metrics obtained from player inputs and game outputs.

Selecting Animations Better

Gillies (2009) points out that the individuality of a real actor's performance should be reflected not only in the appearance and animation of the character, but also in the AI that controls the character's behavior and interactions, in games containing characters based on real actors. I-O HMM (input-output hidden Markov model) is used in this work to learn the transition probabilities for the finite-state machine and the function that selects edges of the motion graph based on the current state. A motion graph allows animations to be generated by sequencing preexisting animations. Each edge of this graph is associated with an animation clip. There is a probability for each edge of the motion graph. A node of the motion graph is a point at which an animation clip can be selected.

Making Agents Human-Like

To make computer-controlled characters believable by having them move like human-controlled characters, Gorman and Humphrys (2006) recorded locations of the character controlled by the human player and clustered these locations. Each of these clusters is a node in the directed graph which has an edge from node i' to node j' if the human-controlled character was observed to move from i' to j'. They used reinforcement learning. The rewards were designed to encourage the computer-controlled character to follow the routes of the human-controlled character.

Using Games to Improve Machine Learning

Greengard (2017) is a brief review of work relating autonomous driving, machine learning, computer games, and simulations. It is much easier to create diverse and unforeseen roads and surroundings fast at a much lower cost in virtual world, to get a large amount of data for machine learning for autonomous driving.

Recognizing Social Context

Li and others (2010) introduce a multiplayer, collaborative version of Tetris. Each of the two players can control one of the two falling pieces. Each player played on a separate computer separated by a shelf in their experiments. They recorded the players' eye movements. The four social contexts considered by them were NN (a novice playing with another novice), NE (a novice playing with an expert), EN (an expert playing with a novice), and EE (an expert playing with another expert). EN and NE are different categories since the type of the first player in these combinations is different, and this matters in interpretation of the statistical information found for the first player in a pair. They found that gaze on self was strongest for players in NN pairs. They found that gaze on self was weakest for expert players when playing with novice players. Action features they used were intended to capture playing style. Action features were found using type of moves (rotations, translations, drops, and downs) and distances associated with these moves on the grid. They used SVM (support vector machine) classifiers. They show that it is possible to recognize social context based on gaze and action features.

Relating Game-Related Preferences to Social-Network Data

Lim and Harrell (2013) used social-networking information to predict the likelihood of players customizing their profile in several ways associated with the monetary values of the players' avatar. They used clustering and SVMs. They show that a strong relationship exists between a player's real-world identity and virtual identity within games.

Automated Story Generation

Martin and others (2018) define *automated story generation* as the problem of automatically selecting a sequence of events, actions, or words, that can be told as a story. They formalize automated story generation as sampling from the probability distribution over successor events when a sequence of events is given. They use a recurrent encoder-decoder network to produce the probability distribution. They introduce *event2sentence*, which is a neural network for translating an event into natural language.

Generation of Game Stages

Nam and others (2022) train reinforcement-learning agents to generate diverse and enjoyable stages of a game. A stage is a series of events in a turn-based role-playing game. They represent each stage using a matrix containing real numbers. An empty stage is represented by a matrix filled with zeros. Actions fill an incomplete stage matrix sequentially by deciding one or more of its elements. The stage-evaluation function serves as the reward function.

Predicting Opponent's Strategy

StarCraft is a real-time strategy (RTS) game requiring tactics, strategies, and resource management. Opponent's territory is not fully visible in this war game due to fog. Park and Cho's approach (Park and Cho 2012) involves sending a scouting unit to the opponent's territory to find information about the opponent's structures and units, so that it can be used for machine learning. They used 13 machine-learning algorithms. These included algorithms using decision trees and neural networks. Opponent's strategy is predicted to be fast or slow. The opponent's strategy is fast if it attacks first, otherwise it is slow.

Camera Selection

Passos and others (2009) demonstrate an intelligent editor agent for deciding shot transition. There can be multiple cameras, e.g., chasing camera, front camera, and high-view camera. The camera used affects what the human player sees on the screen, and this affects gaming experience considerably. The approach in (Passos et al. 2009) uses a neural network for each camera and decides which camera to use in the current situation based on the classifications provided by the neural networks.

Detecting and Adapting to Novelty in Games

Peng and others (2021) point out that policies of reinforcement-learning agents are often fine-tuned to the mechanics of the environment, but assuming that the state space, action space, and transition dynamics of the world do not change over the life of the agent is not practical in many domains. They define *open-world novelty* as a change in the observation types, action types, environment dynamics, or any other change in the world mechanics that makes it different from the world originally used to train the agent. They propose a deep-reinforcement-learning technique for detecting and adapting to open-world novelty in games. Their system maintains two knowledge graphs. One of them represents the state of the world and the other represents the rules of the game. Their system detects novelty by detecting a change to static entities and relations of the state-knowledge graph or to the rule graph.

Automated Creation of Faces of Game Characters

Shi and others (2022) point out that customizing the face of a character is very time-consuming even for experienced players as there are too many parameters whose values need to be adjusted. Their method automatically creates face of a character based on a single photograph of face. Their method transforms the input image into a set of in-game facial parameters. They use deep convolutional neural networks (CNNs).

Detecting Player Burnout

Smerdov and others (2021) point out that physiological data may provide new insights into a player's behavior. They assert that though in-game data can be useful in player-skill assessment, match analysis, match-outcome prediction, and post-match analysis, models trained on in-game data can become obsolete because of new patches or changes in game mechanics. They collected sensor data from humans playing eSports. This data is about pulse, saccades (rapid eye movements between fixation points), muscle activity, galvanic skin response (GSR), mouse activity, keyboard activity, facial-skin temperature, electroencephalogram (EEG), environmental temperature, relative humidity, carbon-dioxide level, pulse-oximeter data, and movements of chair, hand, and head. They used this data and machine learning to predict outcomes of encounters extracted from in-game logs. They used logistic regression, KNN (k-nearest neighbors algorithm), GRU (gated recurrent unit) neural network, and transformer neural network. Their observations include the following: (i) The feature indicating good in-game activity the most is the intensity of gamma waves for the T7 electrode located near the left temple. (ii) Higher heart rate and eye activity increase the player's performance. (iii) The feature most important in predicting that the player is likely to lose the next fight is vertical movement of the chair. (iv) Higher environmental temperature, humidity, and carbon-dioxide level decrease the player's performance. (v) Higher facial-skin temperature, GSR, and pupil diameter lower the probability of winning the next fight, as these are related to a lower concentration, higher mental load, and stress.

Classification of Team Behaviors

A Hidden Markov Model (HMM) is trained for each team behavior (Thurau et al. 2006). They classified observation data into one of five behaviors. The names of these behaviors followed by their descriptions from (Thurau et al. 2006) are as follows: **dribbling** (one player possesses the ball and the other player follows), **given-and-go** (the ball is passed back and forth between two players), **ball retrieval** (one player runs toward the resting ball and passes it to the other player right away), **long pass** (the ball is passed over a longer distance and not returned), and **solo** (the player with the ball does not pass the ball but constantly moves in one direction, and the other player runs alongside).

Sports video game

Definition

Sports video game	A genre of games that replicates how a sport is played in a video game format

History of Madden NFL

The lens of infinite inspiration proposes that instead of looking at a game for ideas, one should look at everything else. If one looks only at a game or games like the one they are creating, the game might seem like an imitation. Instead, look for inspiration in the world. In Jesse Schell's book "The Art of Game Design: A Book of Lenses," the Lens of Infinite Inspiration states that "to use this lens, stop looking at your game, and stop looking at games like it. Instead, (Schell, 2019) look everywhere else." The Lens of Infinite Inspiration asks the following questions:

1. What is an experience I have had in my life that I would want to share with others?
2. In what small way can I capture the essence of that experience and put it into my game?

Madden NFL 19 is a sports video game about the professional American football league. This game captures the experience of a game that some cannot play due to physical handicaps or a lack of means. The game inspires young children to go out and try football in real life. It was created because someone wanted to share an experience

they had with other people (Madden NFL 19, 2018).

The next part of the lens of infinite expression is conveying an experience into the game. In what ways can an experience in the game match the experience the players will feel? The four elements that need to be conveyed are mechanics, story, esthetic, and technology.

Mechanics are rules and controls that the game will have; its what makes a game feel real. *Madden NFL 19* uses many mechanics to enrich the gameplay. The game has a mechanic the allows players to perform skill moves. Skill moves are things like hurdling over a defender or attempting to knock the ball out of the offender's hands. These mechanics give the player a glimpse of what it is like to play in a professional football game. Using mechanics to imitate real life experiences makes a game interesting and unique.

The next element that is used to capture the experience is the story. This can enhance the experience by allowing the player to make choices throughout the game that will determine the ending. In *Madden NFL 19,* there is a story mode that has a young man fighting his way up the ladder to play in the professional league. The player gets a feel on the experience many young men have as they struggle to play professional football. The story is about the life of the game that is portrayed.

The esthetic is how a game looks and sounds. The art and soundtrack will immerse the player into the setting of the game to bring out the experience through their senses. *Madden NFL 19* makes the art as realistic as possible. The developers scanned the players to make the in-game models nearly identical to the real players. They made realistic stadiums with a soundtrack that enhances the experience. If the games' art and sound match the experience, the game will stand out.

The technology is anything that makes the game possible. Inspiration can allow for new technology for a game to be developed. In *Madden NFL 19,* the developers made use of microphones to allow the play to give voice commands to the game. An example of this is saying time-out so the game will call time-out for you. Technology can make a game very unique if one is willing to create new technology to allow for a better experience.

To make a game something special, it needs to have an inspiration, such as personal experience. Imitating other people's inspiration can lead to a game that lacks emotion. Use an experience and the four basic elements to create a game from a unique inspiration.

Making Virtual Reality (VR) Accessible for People with Disabilities

Marco Antonio Martínez Cano, Carolina Padilla Velasco and Steve Bakos
Ontario Tech University, Oshawa, ON, Canada

Synonyms

Accessibility; Augmented reality; Blindness; Cognitive disabilities; Learning disabilities; Mixed reality; Physical disabilities; Sensory disabilities; Virtual reality; Visual impairment

Definition

Virtual reality (VR) is a simulated digital environment that obstructs the real world, creating an immersive experience that can imitate real-world physical properties.

Accessibility in technology refers to the practice of making technology and digital environments usable by as many people as possible.

Physical disabilities are medical conditions that diminish an individual's capacity for physical movement.

Cognitive disabilities or disorders are medical conditions that affect an individual's brain function by limiting the brain's capacity to collect, process, understand, or store information.

Sensory disabilities are neurological disorders that affect the human brain's ability to process sensory information, that is, sight, hearing, touch, taste, and smell.

Introduction

Virtual reality (VR) requires the use of specialized hardware to allow the user to partake in an interactive virtual experience. Examples of this hardware include headsets and motion controllers to interact with the virtual environment. Handling a headset requires the usage of the user's body parts, like neck and shoulders, and upper body strength to support it while being susceptible to movement. These headsets rely on the user's eyes, often leaving little-to-no room for glasses. In addition, motion controllers require the use of the user's hands and arms to take part in most VR gaming experiences, immediately excluding disabled users who may not be able to use this hardware as intended, keeping people with disabilities from participating in most VR experiences. However, as VR technology becomes more popular and its development and techniques are further explored, some alternatives have been proposed to make sure people with disabilities can experience VR. Through the article, examples of accessible approaches for the development of VR gaming will be presented, focusing on people living with physical impairments, visual impairments, and cognitive disabilities.

Disabilities and Their Impact

According to the World Health Organization in World Health Organization (2021), over one billion people (15% of the world's population) are living with some form of disability. This number is growing because of demographic trends, the increasing rate of chronic health conditions, and other causes. Therefore, it is likely that everyone will experience a disability in some form or another at some point of their life. Disabilities can take various forms, physical, cognitive, sensory, or other. Each disability brings its challenges to the individual's life and unique accessibility needs for the user to engage with VR. Headsets are often bulky, causing accessibility issues for users with weak neck and shoulder strength. According to The 360 Guy (2022), VR headsets range in weight from 468 grams (1 lb, 0.5 oz) to 644 g (1 lb, 6.7 oz). Users who cannot support this weight while performing actions required by the VR application have few options.

Motion controllers often require the user to hold them at specific positions, point them in a direction, and make mid-air motions (Heilemann et al. 2021). Disabilities that prevent someone from raising their arms and moving their hands can prevent them from using motion controllers and many VR applications that depend on these controllers for input. An implicit assumption of these motion controllers is that the user has one or both hands available and has fine and gross motor control to perform precise and large movements (Mott et al. 2020). This may not always be the case, as many physical disabilities can severely limit an individual's ability to perform these required motions, thus preventing them from engaging with VR and presenting a significant barrier to entry.

Sensory disabilities can also impact the user's ability to partake in VR. Users with visual disabilities may find text instructions difficult to read, requiring the application to support descriptive audio or additional audio cues to guide them. However, including these additional accessibility features is a choice made by the developers of the application. Conversely, users with auditory disabilities can experience difficulty hearing important sounds or speech and may depend on the application's developers, including subtitles as an accessibility aid.

Each manufacturer of VR equipment has their standards, locking games to specific hardware that may not support the accessibility features a disabled user requires (W3C Working Group 2021). This presents an additional barrier to entry as not having the accessibility of VR hardware standardized across different manufacturers leaves the

inclusion of accessibility features to each manufacturer's discretion.

VR Gaming for People with Physical Impairment

Physical disabilities can prevent individuals from using VR for a variety of reasons. Depending on the disability, different actions required by the virtual environment can be difficult to impossible for a disabled person to perform. Because the VR headset tracks the position of the user's head in 3D space and various applications expect the user to stand, people who cannot stand negatively impact their experience.

WalkinVR is an assistive tool that enables a third party to alter the position of the VR user in 3D space, use action buttons on the controller, or grip game objects (WalkinVRDriver 2022a). For individuals that cannot perform actions such as standing, crouching, or lying prone, WalkinVR also provides assistive functionality that enables users to create additional controller bindings that mimic these actions. By adding this functionality, users with disabilities that prevent these actions can partake in environments that require them (WalkinVRDriver 2022b).

Another accessibility feature WalkinVR provides is adjusting the position of a motion controller in VR. Environments can have physical expectations of the user, such as raising the motion controller to a specific height (e.g., eye or shoulder level) or extending the motion controller a distance away from their body, which a disabled user may find difficult or impossible. The user can also change the scaling of real-world movements to virtual movements (i.e., an 8 cm movement on the real controller can translate to a 30 cm movement within the virtual environment). WalkinVR's functionality of adjusting the motion controller's position and increasing the scaling of real-world to virtual moments enables disabled users to overcome these barriers to entry (WalkinVRDriver 2022c).

And finally, another accessibility issue that WalkinVR addresses is the requirement of using motion controllers to engage with virtual environments. People with disabilities that cannot hold motion controllers can now engage with VR by using their hands as the controller to a limited degree. Integrating a Microsoft Kinect 2.0 or Kinect 360 allows a user's hands to act as a motion controller for environments requiring a player "touching" something within them. The VR environment now uses the position of the user's hands in place of the controller, thus enabling people with disabilities that prevent them from holding or grasping a motion controller to engage with VR (WalkinVRDriver 2022d).

The VR game Half-Life: Alyx, developed by Valve Corporation, is an example of a game with many accessibility options for physically disabled users. Players can choose their dominant hand to wield weapons and play in a seated mode where crouching and standing are done with the controller instead of physical movements (Rad 2020). The game provides additional accessibility features such as subtitles and closed captions, reducing the strength and flickering of lights in-game, and disabling "Barnacle Lift" (i.e., preventing an in-game enemy from lifting the player character off the ground. Instead, the player takes damage and remains in place).

Half-Life: Alyx also lets users change how they select their weapons from the in-game context menu. Instead of using their hand to point at and select a weapon, the user can do this using their head. Disabled users with difficulty with fine motor skills have other options that may be more accessible to them.

VR Gaming for People with Learning Disabilities

The approach of adopting video games as a way for people with cognitive disabilities to develop or improve learning skills has been around for a couple of years, and this approach has been applied to different types of disabilities such as Autism, Dyslexia, Dyscalculia, Dysgraphia, etc. In addition, some video games and mobile applications have been developed with the intention of identifying whether a user might have some type of learning disability rather than

immediately addressing a specific type. Results have shown improvements in the different areas where it has been applied. However, with the recent spread and popularity of VR, specifically in the gaming sector, the development of VR games directed to address cognitive disabilities constitutes the next step for further gaming developers. The possible advantages of a fully immersive gaming experience to enhance and facilitate learning in different areas should be explored to create a more inclusive gaming community and to take advantage of new technologies as a helping tool for people with cognitive disabilities.

A project was founded in 2018 by the US Department of Education, aiming to use VR to help students with learning disabilities in schools all over the country. The University of Kansas developed the "VOISS: Virtual Reality Opportunities to Implement Social Skills" project to address the challenges in the development of social skills for students with disabilities. VOISS uses a VR Head-mounted Display (HMD) set that allows subjects to enter a controlled virtual environment where they can walk around in different locations like hallways, locker rooms, classrooms, etc. Recreating interaction scenarios with computer-driven avatars allows the user to evaluate an interaction's positive or negative consequences. The fundamental goal is to use VR to explicitly teach students social skills and the proper way to apply them in natural environments (Gera 2018).

According to cognitive science, virtual experiences can enhance cognitive flexibility in non-digital environments. To become an adequate learning tool, digital environments must keep a sense of realism. This realism creates a relationship between the consequences of learned actions in a virtual environment and the real world.

Ahn's work intended to elaborate on the effects of combining VR and a computer video game for cognitive-based therapy with a group of 13 children between the ages of 7 and 13 years and the capacity to play a game for 20 min and follow verbal instructions (Ahn 2021). Subjects took part in four sports games using a Wii console and a motion-based VR game. To study the differences in visual-motor integration, the second editions of the Bruininks-Oseretsky Test of Motor Proficiency and Developmental Test of Visual Perception were implemented to analyze changes in function for visual-motor integration and to identify changes in visual perception.

Results showed the effectiveness of VR and computer game-based therapy to approach cognitive disabilities by appealing to visual perception and motor function in children with these types of disabilities, demonstrating a considerable improvement of scores for both examination methods after exposure to VR gaming therapy for specific elements such as visual motor integration and general visual perception.

Research conducted by Kim et al. (2019) focused on VR intervention's effectiveness as a therapy method for people with mild cognitive impairment or dementia, gathering results from 11 different studies highly focused on VR. Kim et al. compared the results from studies that used a full-immersive VR experience to studies using semi-immersive technology and found a small-to-medium effect ratio in patients exposed to VR intervention techniques, especially in factors such as physical fitness, cognition, and emotion. Aiming to set boundaries for a standardized guideline for VR intervention in patients, the research intended to summarize evidence to validate the use of VR in this healthcare area.

VR Gaming for People with Visual Impairment

Most video games rely on visual elements to guide the user, leading to unintended exclusion for people with some degree of visual impairment. Even though some features like screen reading and options for size adjustment exist in some games, these approaches do not ensure people with sight loss can experience gaming to its full extent. The lack of inclusive options increases with emerging technology, which is the case with VR gaming. However, it is important to point out that blind individuals develop other senses to a larger extent, such as hearing,

smelling, and touching. That is why VR gaming is an excellent area of opportunity to enhance the user's experience while gaming without the use of visual stimuli. Making the most of other elements like audio and haptics can ensure an entertaining gaming experience. Recent developments were made to create VR gaming options for the blind community. However, mainstream VR games are not designed to adapt to the needs of people with sight loss.

One game prototype is The Enclosing Dark, created by Gluck and Brinkley in 2020. It is a VR adventure game that was designed as a game option for the visually impaired. Pre-game training teaches the user how to understand the audio and haptics and interact with the virtual environment. Audio and haptics are combined to provide feedback about the invisible landscape where the game takes place. Audio is mainly used to communicate with the user and describe the actions of the player's avatar, from footsteps to rotation. Spatial audio is applied to create a simulation of the natural environment, allowing the user to build a mental map through the auditory output. Haptics is a medium to deliver supplemental information about the virtual environment through three different vibration patterns. The first one is used to aid in the location of obstacles, the second one provides feedback when hitting an enemy, and the third one gives additional information about the surroundings (Gluck and Brinkley 2020).

In 2021, a VR archery game that had no visual elements was created. The main purpose behind it was to assess if early blind adults would show less developed head-trunk coordination, as sensory disabilities have a direct impact on motor development. It was tested by letting early blind and sighted individuals play it and compare the results. The hardware used was the game engine Unity 3D, BOSE over-ear headphones, and a LG Google Nexus 4 smartphone. The user had to lead an arrow to hit the center of a target by a combination of head and trunk rotations around the vertical axis (Esposito et al. 2021).

Also, in 2021, Racing in the Dark was developed. It is a fast-paced VR racing game accessible to the blind community, as it takes advantage of the elements built into the Oculus Quest VR headset. With its haptics, tracking, auditory, and voice systems, a nonvisual experience is provided to the user. The game consists of a car race against four artificial intelligence opponents on a three-and-a-half-mile virtual track. The first one to complete three laps over the track wins. Haptic feedback is the primary source for providing the player with information about the racetrack without any visual input. Also, with the controllers' hand gestures tracking, the player can provide input to the game. In addition, vocal input is used to communicate with the artificial intelligence pit crew. Finally, audio output is used to create a more immersive experience, as it was not suitable for information transmission because it was too slow to create a fast-paced experience (Gluck et al. 2021).

Conclusion and Discussion

It is important to consider the area of opportunity within the design of inclusive VR video games. Nowadays, mainstream VR games are usually not accessible to people with disabilities. However, headsets expand possibilities and allow those types of games to have a lot of potential for making the most of their features and creating an accessible experience for everyone. Elements like haptics, controllers, visual output, and audio output should be considered when designing a VR game. There are a few developments and adaptations of video games to make them accessible. However, the work done is not enough to ensure that VR gaming is accessible for people with disabilities. In addition, the advantages obtained from the use of VR gaming in different therapy techniques have been shown in recent research, highlighting the importance of pushing VR gaming to become more accessible for people with disabilities. Aiming for a more inclusive society and gaming community, people with disabilities can benefit from entertainment improving the state of their condition through VR therapy in some cases.

Mario Kart, an Analysis of Its Absence from Esports

John Hoback[2] and Newton Lee[1,2]
[1]Institute for Education, Research, and Scholarships, Los Angeles, CA, USA
[2]Vincennes University, Vincennes, IN, USA

Synonyms

Racing games

Definition

Mario Kart is a Multiplayer Racing Game created by Nintendo. It allows up to eight players to race to the finish line by using various items to attempt to take the lead.

Introduction

As of December 2021, *Mario Kart 8* is Nintendo's highest selling Switch game, with over 43 million copies sold (Nintendo.co.jp). Despite the popularity and the competitive gameplay, Mario Kart has limited popularity in the professional esports scene. This entry discusses the positive and negative factors effecting Mario Kart in order to determine why it is missing from the professional esports scene (Esports Talks, 2018).

Four Positive Factors

William Collis, author of "Book of Esports: The Definitive Guide to Competitive Video Games," states four main factors that make a game an esports: the player's skills, the community surrounding the game, how accessible the game is to players, and how rewarding the game is to play (Collis, 2020 p.5). Another source from the esports-news.co.uk article titled "What Factors Help Create a Successful Esports Games" states that "Providing a game that is easy to learn yet hard to master, delivering quality audience experiences with spectator modes, title must have widespread appeal, and having simple goals set for players to achieve" (esports-news.co.uk) (Esports News UK, 2021).

In short, the most important factors for an esports game are:

1. Simple to learn but requires skills to master
2. Has a large community
3. Has a simple goal to achieve
4. Must be rewarding to become skilled

How does this relate to *Mario Kart 8?* As stated in the introduction, it is currently Nintendo's highest selling switch game. It would be reasonable to say that it has a large community backing (factor #2). The game is also quite easy to learn for new players but requires a large amount of skills to use items and drift abilities at the right time (factor #1). The goal of the game is to complete four races and earn points to be crowned the winner (factor #3). In the offline mode, when a player wins first place in a grand prix, they are rewarded with a trophy. If they get first place in all four races, they get a gold trophy for mastering the tournament. In online tournaments, the players are randomly assigned to a track. The points you earn either increase or decrease your score on the world leaderboards (factor #4). From this, we can deduce that the game is in line with all four goals.

Four Negative Factors

However, there are four factors that negatively hurt Mario Kart in the esports world. Chris Blain, a writer for Esportstalk.com, listed several reasons the game is missing from professional esports. His first point was the lack of tournaments. Mario Kart tournaments do not have official leagues, unlike many other popular games. The tournaments are mostly fan run, so the prize pools are too low for players to spend the time getting skilled at the game. His second point was the RNG factor. He stated the game has too much randomness and luck, but the game is quite boring without having at least some items available. His third point was that many of the courses are designed to allow players to cheat and take shortcuts, which can present an unfair advantage. His final point was the lack of team elements in the game – a feature that is common in almost all popular esports games (Blain). It should be noted that his fourth point is no longer valid because Nintendo has added team races in a game update.

Blain made some good points in his article. The game relies heavily on RNG. Many of the races could end because another player got lucky. However, luck is a factor that is common in most games. For example, a player could draw a good card right when they need it in Hearthstone. The cheating on tracks is a big factor, but this could be alleviated by either banning the cheatable tracks in official tournaments or adding rules to disqualify players who cheat. From his points, the only negative factor that cannot be easily removed is the lack of official tournaments.

Issues with Tournaments

The biggest negative factor for Mario Kart is the limited number of tournaments. In fact, Nintendo only recently started hosting official Mario Kart tournaments in 2021. They signed an agreement with PlayVS to create an official high school league, but not much has been done otherwise (ign.com). The closest thing that most players get to official tournament is the online matches that Nintendo occasionally host. These tournaments require you to be on the top of the world leaderboard at the end of the 3-day tournament in order to be crowned the winner. The winner of the tournament wins 2500 Eshop credits, which translate to roughly $25, which does not even cover half the cost of *Mario Kart 8*.

The unofficial leagues do not reward much either. According to esportsearnings.com, the highest earning player of 2022 earned $450 for the whole year. This is nothing when compared to Dota 2. The top earner, Mira, won $3,696,653. The 500th place winner made $2800, which is six times what Mario Kart paid out (esportsearnings.com).

Conclusion and Discussion

Mario Kart 8 has the potential to be a professional esports game. It has all the common traits needed to gain popularity. There are certainly some factors that need balancing, such as RNG and issues with track designs. Since Nintendo still actively adds new content to Mario Kart in 2022, there is still a potential. The biggest factor hurting the game's popularity in esports is Nintendo itself. While Epic, Tencent, and other companies have been actively involved in the esports scene since the release of their games, Nintendo has only recently started to allow officially licensed leagues in 2021. They have focused primarily on building tournaments for their other games, such as *Super Smash Bros Ultimate* and *Splatoon 2*, while ignoring their cash cow Mario Kart. The lack of official tournaments means that the winning prizes are too small to be enticing. If professional leagues are to take off, Nintendo must step up, offer bigger prizes, and most of all, listen to their fan base.

Definitions

MEEGA+ is a systematic model to analyze educational games (digital and nondigital ones) in order to evaluate their perceived quality from the students' perspective in the context of computing education (Petri et al. 2016, 2017a).

Introduction

In the last years, games have also been used for different purposes than entertainment, being more and more used in educational contexts (Abt 2002; Connolly et al. 2012; Battistella and Gresse von Wangenheim 2016). Educational games are supposed to be an effective and efficient instructional strategy for teaching and learning in diverse knowledge areas such as mathematics, health, computing, and nutrition (Connolly et al. 2012; Calderón and Ruiz 2015). Especially in

computing education, there is a vast variety of educational games to teach computing competencies mainly in higher education (Battistella and Gresse von Wangenheim 2016). The majority are digital games, principally PC (Personal Computer) games, with a considerable trend also to nondigital ones (paper and pencil, board games, etc.). Predominant are simulation games, which allow students to practice competencies through the simulation of real-life situations in a realistic environment while keeping them engaged in the game (Battistella and Gresse von Wangenheim 2016). On the other hand, there also are several games designed to teach computing aiming at learning objectives at lower cognitive levels. Typically, these games are used to review and reinforce knowledge taught beforehand using different instructional strategies (Battistella and Gresse von Wangenheim 2016). These games are expected to be an effective and efficient strategy for computing education (Backlund and Hendrix 2013). However, these claims seem not rigorously established as most evaluations of educational games are performed in an ad hoc manner in terms of research design, measurement, data collection, and analysis (Calderón and Ruiz 2015; Petri and Gresse von Wangenheim 2017) due to the absence of models that provide a more systematic support for the evaluation of educational games (Petri and Gresse von Wangenheim 2016). Existing models for the evaluation of games typically focus only on specific quality factors, such as usability (Omar and Jaafar 2008), engagement (Brockmayer et al. 2009; Norman 2013), or player experience (Denisova et al. 2016; Abeele et al. 2016), not providing a more comprehensive analysis of the games' quality, and, in particular, not evaluating their impact on learning, being one of the main objectives of educational games. In this context, the MEEGA model (Savi et al. 2011) being developed since 2011 seems to be the most widely used evaluation model in practice (Calderón and Ruiz 2015; Petri and Gresse von Wangenheim 2017). MEEGA is a model developed for the evaluation of the quality of educational games in terms of motivation, user experience, and learning (Savi et al. 2011). Yet, although demonstrating an acceptable validity and reliability, a more comprehensive analysis of the initial version of the MEEGA model has identified improvement opportunities mainly related to an overlap of theoretical concepts of the factors motivation and user experience (Petri et al. 2017b). Consequently, the model has been revised resulting in a new version, the MEEGA+ model, which evaluates educational games in terms of usability and player experience. Thus, this article presents the design and evaluation of the MEEGA+ model, as an evolution of the MEEGA model proposed by Savi et al. (2011).

The MEEGA+ Evaluation Model

The objective of the MEEGA+ model is to analyze educational (digital and nondigital) games in order to evaluate their perceived quality from the students' perspective in the context of computing education (Petri et al. 2016, 2017a).

Evaluation Dimensions

With respect to this objective, the perceived quality is evaluated in terms of quality factors and dimensions. Based on a literature review (Petri and Gresse von Wangenheim 2017) and a systematic analysis of the initial version of the MEEGA model (Petri et al. 2017b), a set of dimensions was defined to be measured by the MEEGA+ model: focused attention, fun, challenge, social interaction, confidence, relevance, satisfaction, usability, and perceived learning (Table 1). The dimension usability is further fragmented into five subdimensions: learnability, operability, aesthetics, accessibility, and user error protection. A detailed description of the definition of dimensions can be found in Petri et al. (2016, 2017a).

Measurement Instrument Items

Data collection is operationalized through a measurement instrument (questionnaire). The measurement instrument items were derived based on the defined dimensions, improving the initial

MEEGA+, Systematic Model to Evaluate Educational Games, Table 1 MEEGA+ measurement instrument items

Dimension/Subdimension		Item No.	Description
Usability	Aesthetics	1	The game design is attractive (interface, graphics, cards, boards, etc.)
		2	The text font and colors are well blended and consistent
	Learnability	3	I needed to learn a few things before I could play the game
		4	Learning to play this game was easy for me
		5	I think that most people would learn to play this game very quickly
	Operability	6	I think that the game is easy to play
		7	The game rules are clear and easy to understand
	Accessibility	8	The fonts (size and style) used in the game are easy to read
		9	The colors used in the game are meaningful
		10	The game allows customizing the appearance (font and/or color) according to my preferences
	User error protection	11	The game prevents me from making mistakes
		12	When I make a mistake, it is easy to recover from it quickly
Confidence		13	When I first looked at the game, I had the impression that it would be easy for me
		14	The contents and structure helped me to become confident that I would learn with this game
Challenge		15	This game is appropriately challenging for me
		16	The game provides new challenges (offers new obstacles, situations, or variations) at an appropriate pace
		17	The game does not become monotonous as it progresses (repetitive or boring tasks)
Satisfaction		18	Completing the game tasks gave me a satisfying feeling of accomplishment
		19	It is due to my personal effort that I managed to advance in the game
		20	I feel satisfied with the things that I learned from the game
		21	I would recommend this game to my colleagues
Social interaction		22	I was able to interact with other players during the game
		23	The game promotes cooperation and/or competition among the players
		24	I felt good interacting with other players during the game
Fun		25	I had fun with the game
		26	Something happened during the game (game elements, competition, etc.) which made me smile
Focused attention		27	There was something interesting at the beginning of the game that captured my attention
		28	I was so involved in my gaming task that I lost track of time
		29	I forgot about my immediate surroundings while playing this game
Relevance		30	The game contents are relevant to my interests
		31	It is clear to me how the contents of the game are related to the course
		32	This game is an adequate teaching method for this course
		33	I prefer learning with this game to learning through other ways (e.g., other teaching methods)
Perceived learning		34	The game contributed to my learning in this course
		35	The game allowed for efficient learning compared with other activities in the course

version of the MEEGA questionnaire, and customizing and unifying existing standardized questionnaires found in literature (Savi et al. 2011; Keller 1987; Tullis and Albert 2008; Sindre and Moody 2003; Sweetser and Wyeth 2005; Poels et al. 2007; Gámez 2009; Takatalo et al. 2010;

O'Brien and Toms 2010; Wiebe et al. 2014; Fu et al. 2009; Mohamed and Jaafar 2010; Zaibon and Shiratuddin 2010; Zaibon 2015; Brooke 1996; Davis 1989). Table 1 shows the defined items for the MEEGA+ measurement instrument for each dimension/subdimension.

Response Format

The response format of the items of the MEEGA+ measurement instrument is a 5-point Likert scale with response alternatives ranging from strongly disagree to strongly agree (DeVellis 2016). The use of the Likert scale in its original 5-point format allows to express the opinion of the individual (student) under the object of study (educational game) with greater precision, besides allowing the individual being more comfortable to express their opinion, using a neutral point and, thus, increasing the quality of the answers (Dawes 2008).

Research Design

In order to conduct the evaluation in a quickly and nonintrusive way not interrupting the normal flow of the class, a case study design was chosen for the evaluation that allows an in-depth research of an individual, group, or event (Wohlin et al. 2012; Yin 2017). The general study design is a one-shot post-test only design, in which the case study begins with the application of the treatment (educational game) and afterwards the MEEGA+ questionnaire is answered by the students to collect the respective data. Adopting this research design, the evaluation objective is assessed based on the students' perceptions (perceived quality).

Data Analysis

Data collected in the case study are analyzed in terms of frequency distribution (through bar graphs) and central tendency (median) for each quality factor (usability and player experience) and their dimensions (Fig. 1). The MEEGA+ model provides a spreadsheet for the analysis of the data collected, assisting in the organization of the information and automatic generation of graphs visualizing the results of an evaluation.

The complete material of the MEEGA+ model is available in English, Brazilian Portuguese, and Spanish at: http://www.gqs.ufsc.br/meega-a-model-for-evaluating-educational-games/ under the Creative Commons License.

Evaluation of the MEEGA+ Model

In order to evaluate the reliability and construct validity of the MEEGA+ measurement instrument, 40 case studies were conducted, evaluating 18 different games applying the MEEGA+ model with a population of 718 students (Petri et al. 2018).

Reliability refers to the degree of consistency of the instrument items, typically, measured through the Cronbach's alpha coefficient (Trochim and Donnelly 2008). Analyzing the data collected, the value of the Cronbach's alpha for all items of the MEEGA+ measurement instrument is considered excellent ($\alpha = 0.928$). This result demonstrates that the answers to the items are consistent and precise, indicating the reliability of the MEEGA+ measurement instrument.

Construct validity refers to the ability to actually measure what it purports to measure, involving convergent and discriminant validity, which is obtained through the degree of correlation between the instrument items (Trochim and Donnelly 2008). In order to identify the number of factors that represents the responses of the items of the MEEGA+ measurement instrument, a factor analysis was performed. The results indicate that the structure of the MEEGA+ is based on an evaluation model with two quality factors and their dimensions, as presented in Fig. 2.

Analyzing the correlation between the items of the two quality factors (usability and player experience), the results show that there is a large correlation between most of the items within each quality factor. This indicates that a convergent validity can be established for the two quality factors (usability and player experience). In the same way, items of different quality factors present a small correlation, and, thus, provide evidence of discriminant validity. This indicates that the measurement instrument of the MEEGA+

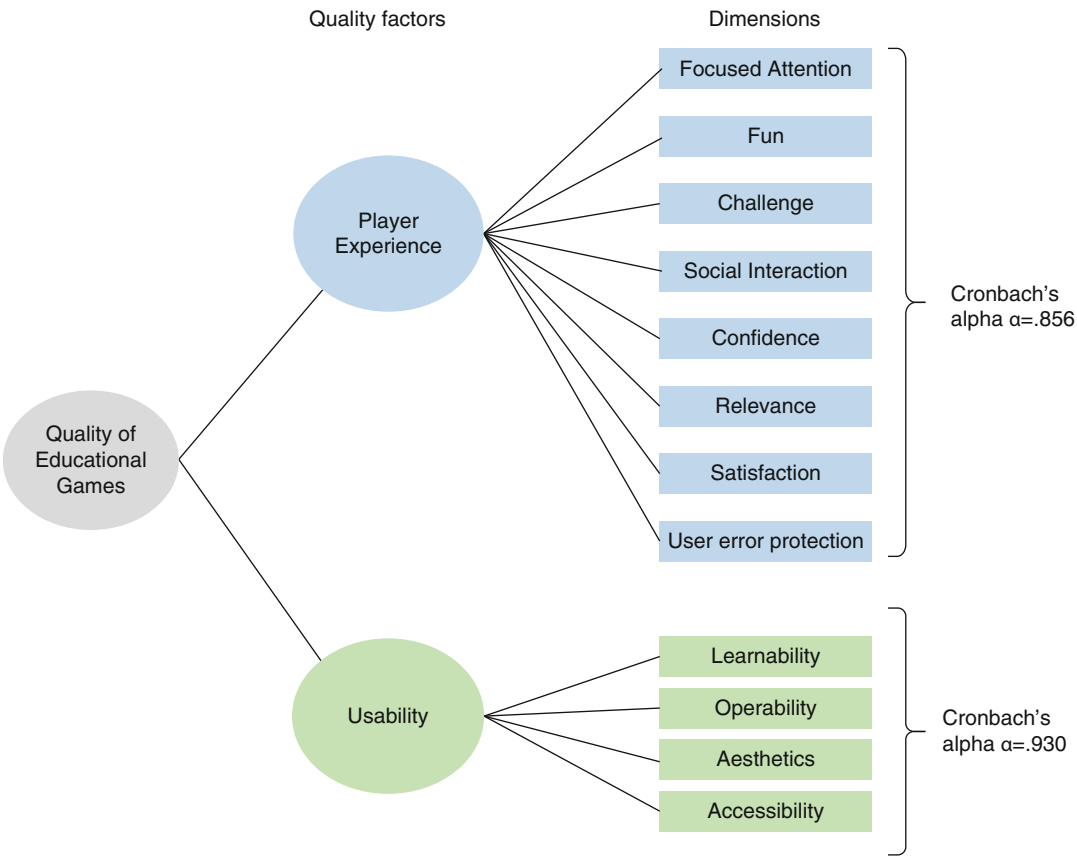
MEEGA+, Systematic Model to Evaluate Educational Games, Fig. 1 Example of data analysis graph provided by the MEEGA+ model



MEEGA+, Systematic Model to Evaluate Educational Games, Fig. 2 Decomposition of the quality of educational games in the MEEGA+ model

model is valid for evaluating the quality of educational games.

Conclusions

The MEEGA+ model, an evolution of the MEEGA model, aims at evaluating the perceived quality of educational games focusing on usability and player experience from the students' perspective in the context of computing education. Results of a statistical evaluation of the MEEGA+ measurement instrument demonstrate satisfactory reliability and construct validity. Thus, the MEEGA+ model can provide a reliable and valid measurement instrument for game creators, instructors, and researchers in order to evaluate the quality of educational games as a basis for their improvement and effective and efficient adoption in practice. And, although it has been originally developed for the evaluation of games for computing education, the MEEGA+ model can be used and adapted for the evaluation of games to teach other knowledge areas.

Dynamic difficulty adjustment; Dynamic game balancing; Pacing

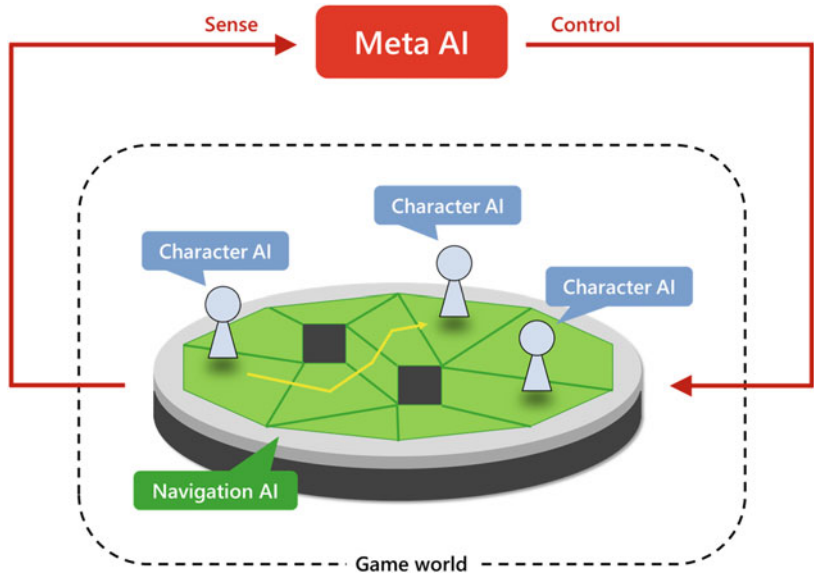
Definition

Meta Artificial Intelligence (Meta AI, as known as AI Director) is the set of processes used to control a whole game from a meta perspective.

Introduction

The main AI used in games can be classified into three types (Miyake 2017): character AI (see the ▶ "Character Artificial Intelligence" chapter) for representing characters, navigation AI (see the ▶ "Navigation Artificial Intelligence" chapter) for making environment information easy to handle, and Meta AI, which is described in this entry.

Meta AI is AI for controlling the whole game from the meta perspective (Fig. 1). For example, difficulty is generally adjusted in advance based



Meta Artificial Intelligence and Artificial Intelligence Director, Fig. 1 The basic idea of Meta AI. Character AI and Navigation AI work inside the game world. On the other hand, Meta AI controls the whole game from the meta perspective

on several standards such as "easy," "normal," and "hard." However, by introducing Meta AI, it is possible to dynamically change the difficulty and game balance according to the player's estimated emotions calculated by the gameplay data, making it possible to realize the optimum difficulty setting for individual players and game situations (see the "Combat Meta AI" section). In addition, it is difficult to optimally configure all events and objects beforehand in the wide game environment referred to as an open world. Using Meta AI makes it possible to dynamically control the events, characters, and other game objects encountered by players (see the "Non-combat Meta AI" section). Furthermore, Meta AI can make fun games actively through not only controlling the existing game but also generating contents such as music, terrain, or stories (see the "Conclusion and Discussion" section).

Meta AI Versus AI Director

AI Director is a similar term to Meta AI.

AI Director is a technology introduced for realizing adaptive dramatic pacing in order to increase the ability to replay (Booth 2009a, b). In Left 4 Dead (Booth 2008), this was accomplished through AI, which controls the intensity of the player by controlling the spawning pace of enemy characters.

Meanwhile, Meta AI is a technique advocated by Will Wright (2005) and utilized in his games such as The Sims (Wright 2000). According to Wright, Meta AI creates an experience by information flow, pacing, and a simple player model. This includes a peer AI, which controls agents, and a sub-AI, which governs simulations. Therefore, Meta AI is not limited to battles and can be understood to be an AI, which broadly controls the whole game.

Accordingly, in this entry AI Director is defined that optimizes certain parts of a game as a type of Meta AI and interpret the technology referred to as AI Director also as Meta AI.

Combat Meta AI

In this section, the authors describe Meta AI in a combat scene. Combat Meta AI can be broadly classified as (1) an approach that dynamically adjusts the difficulty of the game according to the changing battle situation and the state of the player throughout the battle and (2) an approach that dynamically adjusts the behavior, placement, and other game parameters of a nonplayer character (NPC) depending on the positional relationship of the characters and the battle situation. In this section, this is referred to as

pacing Meta AI, and tactical Meta AI, respectively.

Application of many of the methods introduced in this section is envisaged in situations where players and NPCs battle in the game, such as first-person shooter (FPS) fighting games or role-playing games (RPG). However, they are widely applicable to games that are designed to make players challenge the game system or NPC in some way, such as puzzle games, card games, board games, and other game parameters.

Pacing Meta AI

When and in what number should enemies make an appearance in a game where the enemies appear and are defeated one after another, such as in Space Invaders (Nishikado 1978)? For example:

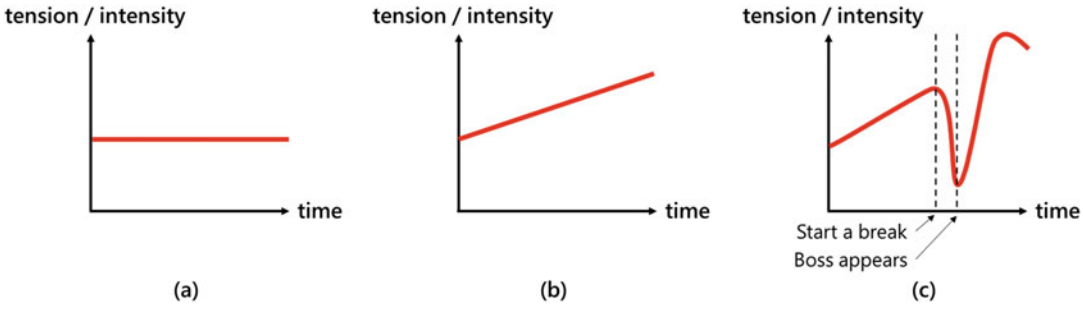
(a) Ten enemies appear per minute and continue to do so thereafter.
(b) Ten enemies appear in the first minute, 20 enemies appear in the next 1 min, and the number of enemies that appear continues to increase at the same pace.
(c) Ten enemies appear in the first minute, 20 enemies appear in the next 1 min, and after a 5-s break, the boss appears.

Of these cases, the third is an adequate pace for the flow of the game and would probably be found interesting. Figure 2 shows the player's expected chart of tension or intensity (called "interest curve") for each cases. Case (c) makes change that is more adequate in speed of the tension than others by using two events. Such game design techniques are widely known as pacing (Schell 2014; Rogers 2014).

Dynamic Difficulty Adjustment

In many games, the pace and difficulty of the game is predetermined by the game designer and does not change dynamically during play. The game designer carefully adjusts the parameters such that most players (or a representative player) experiences enjoyment. As a result, ten enemies appear in the first minute, and there is a 5-s break before a boss. However, as the skills of players and the game situations are diverse, it is not easy for every player to enjoy exactly the same content. Depending on the person, the game may be too easy or boring or it may be too difficult and make the player abandon the game. The basic idea of pacing Meta AI is to dynamically control the contents of the game according to the skill of the player and the game situation, such that various players experience a more interesting game. Within pacing Meta AI, the particular function that dynamically adjusts the difficulty level is called dynamic difficulty adjustment (DDA).

Various approaches are proposed for the method of creating a pacing Meta AI. The most classical method is to make difficulty adjustment rules in a form integrated with the game system. For example, Xevious (Endo et al. 1983) implements a simple Meta AI (Miller 2004; Cerny et al. 2005; Miyake 2017). The player's hidden "difficulty" evaluation score defines the enemy



Meta Artificial Intelligence and Artificial Intelligence Director, Fig. 2 Examples of the interest curve. (**a**) Enemies appear in a constant pace. (**b**) Number of enemies increases in a constant pace. (**c**) Using the pacing technique with the "Start a break" and "Boss appears" events

appearance pattern like "if the difficulty is 10 then three Type-A enemies appear" and "if the difficulty is 20 then four Type-A and five Type-B enemies appear." As long as the player proceeds in the game, increasingly stronger enemies appear, but when the player is defeated, the enemies return to weakness. This dynamically realizes a degree of difficulty that is just right for the player.

Emotion-Based Methods

In recent years, methods of separating the Meta AI from the game system and indirectly controlling it by digitizing the player and the game situation have been developed. In Left 4 Dead, Meta AI carries out pacing based on "emotional intensity" in order to realize repeated game playability and maintain interest (Booth 2009a, b). For example, if a player is damaged by an enemy, the evaluation value of emotional intensity increases in proportion to the amount of damage. The game flow is divided into four phases (build up, sustain peak, peak fade, and relax) in order to pace the emotional intensity throughout the game and the phases shift according to a player's behavior and emotional intensity. A similar Meta AI has been introduced in Warframe (Sinclair and McGregor 2013), where the speed of increasing intensity changes according to the growth of the player character (Brewer et al. 2013; Brewer 2014). Satoi and Mizuno proposed a Meta AI using a two-dimensional emotion model composed of "hope of winning" and "fear of losing" to measure and influence the player's various emotions (Satoi and Mizuno 2019). For example, in an action game, if the battle becomes deadlocked, Meta AI estimates the player's current emotion as bored and then tries to change it toward the opposite side of the emotion map by adjusting the enemies' behavior.

Balancing the Skills and Challenges

In the cases mentioned so far, the authors have focused on the pattern of change in difficulty and intensity according to the game progression, but it is also important to balance the skills of players and challenges. If players are to enjoy the game over a long period, situations should be avoided where beginners continue to fight strong enemies or advanced players are matched with weak enemies. Such a concept is modeled as flow theory and the state where the skill and the challenge are balanced is called a flow state (Csikszentmihalyi 1990). Flow theory has influenced game design theory and the DDA method (Salen and Zimmerman 2003; Hunicke and Chapman 2004; Chen 2007). Additionally, a framework for designing games to facilitate the achievement of a flow state has been proposed (Cruz and Uresti 2017).

The balance between the skill of the player and the challenge is considered to be particularly important in games where pacing cannot be based on the number of enemies spawned and the outcome of the game greatly depends on player skill, such as in fighting games. Therefore, several techniques for dynamically adjusting the behavior patterns of enemy characters in fighting games have been proposed in order to match enemy characters with players such that beginners and intermediate players can improve their skill while enjoying gameplay more. Demediuk et al. proposed an enemy AI that realizes DDA by trying to bring the difference in health points (HP) between the player and the enemy close to zero by changing the action selection policy and the Monte Carlo Tree Search (MCTS) evaluation function (Demediuk et al. 2017). In addition, Ishihara et al. introduced a term for reliability of behavior into the MCTS evaluation function and adjusted parameters according to the game situation, thereby realizing an enemy AI that can play with skills similar to that of the player and which seems natural (Ishihara et al. 2018).

Focusing on the Overall Engagement

Xue et al. proposed a method for increasing the overall engagement of a level-progression game such as a puzzle game. This method increases the cumulative number of levels played until the player leaves the game and the total duration of gameplay time. This was implemented it in a match three game released by Electronic Arts (Xue et al. 2017). The game progress is modeled as a stochastic graph composed of level up

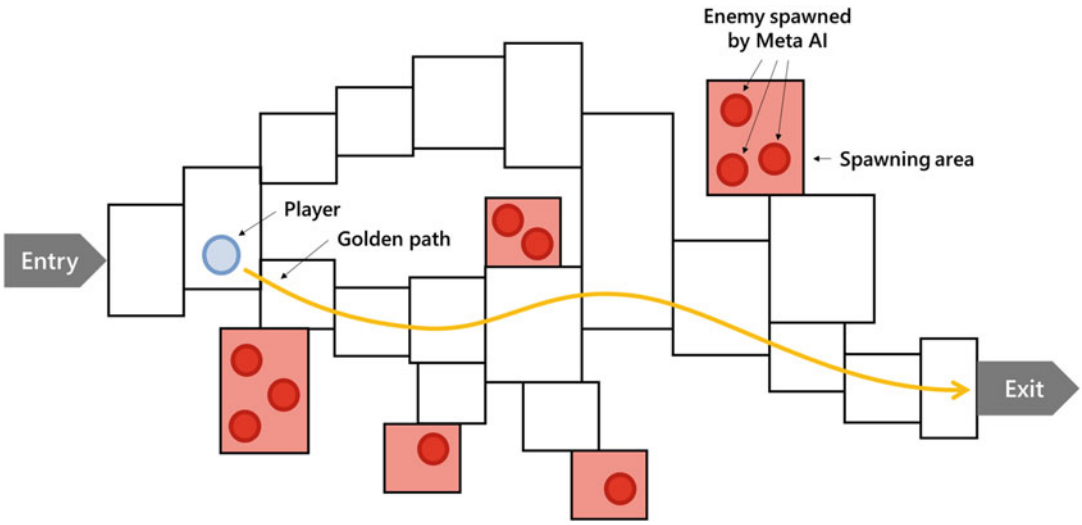
transition, retry transition, and churn transition. The optimum degree of difficulty in each state is calculated by dynamic programming.

Tactical Meta AI

In the previous section, the authors discussed a method of deciding when and by how much to adjust the contents of a game. In action games, real time strategy (RTS) games, and FPS, in which a battle develops in a vast virtual space, it is necessary to take into account "where" the game contents are to be adjusted, that is, the spatial element. For example, when you want to make an enemy NPC appear (spawn) to increase the intensity for a player, it makes no sense if it spawns at a distant location the player passed some time ago. Conversely, if the NPC spawns suddenly in front of the player, it probably causes a sense of discomfort or unnatural. Therefore, in game design it is necessary to calculate a "suitable location" at which to spawn the enemy NPC. There are a great number of methods for constructing tactics and strategies in game AI (Robertson and Watson 2014; Rabin 2017). In this section, the authors introduce some examples of tactical Meta AI that dynamically adjust the behavior, placement, and other characteristics of NPC according to the position of the character or battle situation.

Deciding Spawning Position

In Left 4 Dead (Booth 2009a, b), players move towards the exit while fighting enemy NPC within a level of intricate terrain. However, Meta AI dynamically spawns several kinds of enemy NPC and weapon items in order to realize unexpected game play that can be repeated many times. For example, the majority of enemies, which are called mob, spawn in areas close behind the player and are not directly visible. Meanwhile, boss enemies are spawned in areas that are close to the player and are not directly visible on the player's predicted path of travel (referred to as "Golden path") (Fig. 3) (Jack and Vehkala 2013). In order to realize such spawning, it is necessary to dynamically analyze the positional relationship between the terrain and the player. Left 4 Dead models terrain information for the Meta AI. First, the terrain is divided into a number of subareas. Then information for each subarea for the remaining distance (flow distance) to the exit is embedded using a navigation mesh. Next, the subarea around the player is dynamically calculated. This is called an active area set (AAS) and



Meta Artificial Intelligence and Artificial Intelligence Director, Fig. 3 An example of enemy spawning by Meta AI. Spawning areas are close to the Golden path and invisible by the player

signifies the entire area to be handled by the Meta AI. Combining AAS and flow distance makes it possible to easily and dynamically calculate places suitable for spawning enemies and items.

Combination with Procedural Level Generation

A similar mechanism is introduced in Warframe (Brewer et al. 2013; Brewer 2014), but in contrast to Left 4 Dead, levels are automatically generated. Therefore, an influence map is used to analyze the movement status of players instead of flow distance. Using the position of a player as a heat source, the temperature of the areas surrounding the player are matched to that heat source producing areas where the temperature rises or falls as the player moves. The area where the temperature rises is regarded as the destination to which the player is heading and in which enemies spawn and the area where the temperature falls is regarded as the place from which the player moves away and enemies there are stopped or deleted.

Natural Cooperating

Meanwhile, in the Meta AI of Final Fantasy XV (Tabata 2016) attention is given to the behavior of ally NPCs (Miyake 2018). When a player and three ally NPCs fight together, the Meta AI analyzes the battle situation and directs an appropriate ally NPC to help the player when in a difficult situation or to follow when the player is running away. This avoids unnatural behaviors such as three allies suddenly coming to help the player all at once and realizes a more natural cooperative behavior.

Noncombat Meta AI

In this section, the authors describe cases of Meta AI with a focus on elements not directly related to combat scenes.

In games with very extensive levels, which are called open worlds, it is difficult for a game creator to appropriately arrange all events in advance. Accordingly, in Far Cry 4 (Hutchinson and Méthé 2014), Meta AI is utilized as an encounter manager and objects are arranged so that various things occur as emergent events based on "location and area," "time of day and weather," "frequency," "priority and probability," and other factors (Varnier 2014). As a result, events such as a soldier and an elephant starting to battle and the elephant overturning a jeep occur irrespective of the player's behavior. Moreover, objects such as prisons and animals are dispersed to have a density that results in players encountering events at an appropriate frequency. In addition, by world profiling and adaptive spawning, the number of scavenger animals is increased when there is a big battle.

In Assassin's Creed: Origins (Guesdon and Ismail 2017), Meta AI was utilized in order to make maximum use of limited resources in a vast terrain and at the same time to make the characters feel as realistic as possible (Lefebvre 2018). Objects in games are broadly divided into two types, moving objects (dynamic objects) such as animals and vehicles and nonmoving objects (static objects) such as bases and garages. For efficient searching, in Assassin's Creed: Origins, dynamic objects can be optimally arranged by dividing the game environment according to invisible destination objects called "station" and "child position." Stations own some child positions, and unoccupied stations are selected by a dynamic object such as a character. At this time, the density of objects is controlled with uniformly sized cells dividing the level. The numbers of dynamic objects existing in one cell are managed simultaneously by Meta AI.

Conclusion and Discussion

In this entry, the authors explained Meta AI, which is an AI that controls the entire game. They classified and explained the two types of combat Meta AI: pacing Meta AI, which controls pacing according to the progress of the game, and tactical Meta AI, which controls spatial tactical behavior. In addition, they explained that the occurrence of events during the game and the arrangement of objects, and other game elements were controlled by noncombat Meta AI. In this section, they conclude the entry by considering

the direction of the future development of Meta AI.

Important functions of Meta AI include (1) understanding the player and the game situation and (2) controlling the contents of the game.

For understanding the player and the game situation, algorithms to calculate the state (intensity) of the player from the data obtained from the game controller input are built ad hoc; however, it is costly to construct the model this way and difficult to ensure accuracy. In recent years, there have been many extensive collections of large-scale game play data using telemetry and their utilization is progressing in visualization of data (Pascale 2016), game balance adjustment (Mouret and Athanassoff 2018), and cheat detection by deep learning (McDonald 2018). Furthermore, approaches to measure the physiological information of players (biofeedback with respect to the game) and more direct estimation of the player's psychological state are promising. For example, Ambinder created a version of Meta AI in Left 4 Dead 2 in which the player's skin conductance level (SCL) was used as the intensity. In a comparative experiment with conventional versions, it was found that the version using biofeedback had higher player satisfaction (Ambinder 2011). It is expected that Meta AI will be able to acquire more useful information by developing methods to increase the amount, quality, and processing of data in the future.

For controlling of the game contents, integration with procedural content generation (PCG) technology is considered important. By using PCG, Meta AI will be able to create the game worlds as well as control the existing game world. For example, PCG is useful to make unique experience to each player because it can change games dynamically. However, PCG technology needs the reference parameter for deciding how to change game contents for each player. If Meta AI guesses the player is angry and it wants the player to become more excited, Meta AI may ask the procedural music system to make the BGM more spectacular and may ask the procedural conversation system to make the enemy's dialogue to fuel the player's excitement. Many PCG technologies have been proposed for every possible component in the game, such as game rules, stories, quests, terrain, music, and others. (Shaker et al. 2016; Short and Adams 2017). In addition, in the game industry, the proliferation of procedural techniques is proceeding in many titles, including Warframe and Far Cry 4 as was previously discussed, and No Man's Sky (Murray et al. 2016). By combining Meta AI and procedural technology, it is possible to realize a different procedural generation of the gaming experience for each player.

In this way, the capabilities of Meta AI to realize more interesting games are dramatically increasing. Designing interesting games by utilizing these technologies will be a challenging future work. Additionally, the importance of developing Meta AI technology in both theory and practice is likely to increase further.

Mindfulness; Video games; Virtual reality

Definition

Virtual reality (VR) is "A high-end user-computer interface that involves real-time simulation and interactions through multiple sensorial channels" (Burdea Grigore and Coiffet 1994).

Mindfulness is defined as the intentional paying attention to the present moment (Kabat-Zinn and Hanh 2009).

Introduction

Mindfulness is characterized by positive emotional states and well-being (Brown and Ryan 2003), and it is researched in many contexts such as health, business, and education (Aviles and Dent 2015). Mindfulness results in being more sensitive to the environment and more open to new information (Langer and Moldoveanu 2000a, b). With the advent of virtual reality and wide use of digital applications, the research on mindfulness in virtual reality and other digital applications is also gaining importance.

There is already a considerable amount of applications in the mobile market targeting solely mindfulness, which have variety of features, support different platforms, and have free or paid versions (Plaza et al. 2013). These interactive applications are mostly used as support tools for the nurturing of mindfulness (Sliwinski et al. 2017). Although more research is needed on the interaction between technology and mindfulness, research shows that mobile-based electronic interventions for mindfulness is potentially effective for stress reduction (Lyzwinski et al. 2017).

Mindfulness in Serious Virtual Reality Applications

There are several studies which show that virtual reality systems and their applications help inducing mindfulness or increase people's mindfulness skills, which in return leads to improved well-being. For instance, augmenting mindfulness in chronic pain patients by the use of a virtual reality system was found to be effective in reducing chronic pain (Gromala et al. 2011). In another study, using virtual reality was shown to be more effective than nonvirtual reality condition in people's learning of mindfulness-based stress reduction (Gromala et al. 2015). Similarly, virtual reality supported mindfulness meditation environments were shown to increase mindfulness skills and psychological well-being (Crescentini et al. 2016). In a case study it was shown that virtual reality-supported mindfulness intervention decreases negative feelings along with urges to commit suicide or self-harm (Nararro-Haro et al. 2016). Other attempts include developing virtual reality systems that aim to improve mindfulness with enjoyable experiences (Amores et al. 2016) and virtual reality systems that are combined with neurofeedback to provide deep relaxation, presence and deep levels of meditation (Kosunen et al. 2016).

Mindfulness in Digital Games

Games may be considered at the intersection of technology and mindfulness, in the sense that they may provide full immersion and engagement for the player leaving little to no cognitive room for worrying or other thoughts (Sliwinski et al. 2017). Although application of mindfulness to the digital games context is relatively new, there are a few studies that incorporate mindfulness theory to video game research. Some of these studies approach the topic from a theoretical perspective, and mainly examine the relation between mindfulness and other user experience constructs. For instance, one study showed that mindfulness was positively associated with frequency of game play, length of game play sessions, total number of games played, and the age begun gaming (younger meaning higher scores) (Gackenbach and Bown 2011). Another study investigated the relationship between social anxiety and state mindfulness in online first person shooter (FPS) games (Gavriloff and Lusher 2015). It was found that more socially anxious players were less mindful in the game. Finally, a project shows that how an innovative use of *Minecraft* with mindfulness

principles may contribute to digital story telling (Butler et al. 2016).

There are also other studies, which approach video games as tools for improving mindfulness. For instance, researchers provided several examples for how digital games can improve mindfulness (Sliwinski et al. 2015). Another study describes how procedural content generation-driven games may increase mindfulness of the players and help learning (Smith and Harteveld 2013).

Although scarce, there is also some research on mindfulness and virtual reality games. For instance, one study examined whether a gamified virtual reality system helps gamers learn about mindfulness practices (Choo and May 2014). Another study explains the design of a virtual reality game to help people practice breathing exercises and mindfulness (Patibanda et al. 2017).

Conclusion and Discussion

Taken together, these studies show that there is potential for use of virtual reality in improving mindfulness and wellbeing. Although mindfulness in virtual reality and games appear to be separate lines of research, it is likely that these lines of research will intersect in future.

Mindfulness in computing is a relatively fresh research area with limited number of studies, and the literature on mindfulness in virtual reality games is even scarcer. Thus, more research is needed to understand the processes related to mindfulness in virtual reality and other digital applications. The use of neurofeedback in mindfulness-related virtual reality gaming looks promising for future applications. From a theoretical perspective, the associations between mindfulness and long-studied phenomena such as immersion, flow, and engagement in virtual reality domain might also provide interesting future research directions. However, the use of virtual reality is not widespread as of the time of this writing. Moreover, to the best of our knowledge there are no studies that examine the acceptance or long-term adoption of these systems. Thus, research on the long-term acceptance of virtual reality systems might be needed before delineating the processes about mindfulness in virtual reality.

Definitions

Introduction of Minkowski-Lorentz spaces to simplify Euclidean 2- or 3-dimensional problems.

Introduction

The Apollonius problem is the determination, in a plane, of a circle tangent to three given geometric circles which corresponds to $2^3 = 8$ Apollonius cases using oriented circles. The use of the Minkowski-Lorentz space permits to choice one over eight cases. Moreover, it generalizes when an oriented circle becomes an oriented line, the new number of solutions is given using the same algorithm whereas the new number of solutions is multiplied by 4 in the usual Euclidean affine space. The centers of the circles tangent to two given circles are on a conic. So, solving one of the Apollonius problems (with oriented circles) leads to the computation of the intersection of two conics whereas the problem is linear on the circles

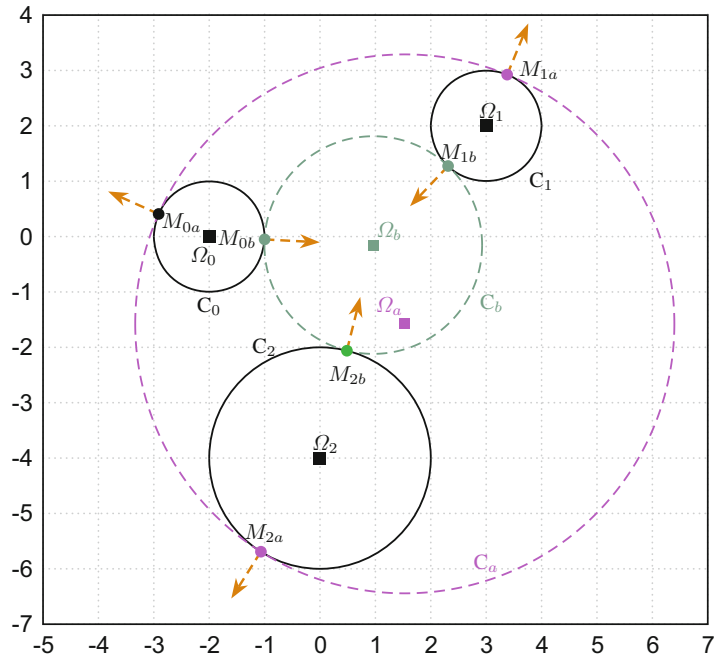
space Λ^3 in the Minkowski-Lorentz space $L_{3,1}$. The Dupin problem is the determination of a surface tangent to three given oriented spheres in $\mathcal{E}_3$. The surface is called a Dupin Cyclide (Darboux 1873, 1887, 1917; Dupin 1822; Dutta et al. 1993; Forsyth 1912; Garnier 2007; Pratt 1990, 1995); its degree is at most 4. To determine the Dupin cyclide, the computation of the two Dupin cyclide principal circles in a plane is necessary. Then, to solve Dupin problem leads to solve the Apollonius problem. One can define a Dupin cyclide as a canal surface in two different equivalent ways. A Dupin cyclide is the envelop of a one-parameter family of oriented spheres centered on a conic (Druoton 2013; Druoton et al. 2013a, 2014; Forsyth 1912; Langevin et al. 2015). As a cubic Dupin cyclide is the envelop of one-parameter family of oriented spheres centered on a parabola, the authors generalize and solve this problem in $\mathcal{E}_2$ and $\mathcal{E}_3$ in section "Family of $n-1$-Spheres Centered onto a Parabola of $\mathcal{E}_n$". To simplify the solving of these problems, the authors use the Minkowski-Lorentz space (Bécar et al. 2016; Druoton et al. 2013b; Garnier and Bécar 2017; entry "▶ Theory of Minkowski-Lorentz Spaces"; Garnier et al. 2017, 2018; Garnier and Druoton 2013)

$n-1$-Spheres Tangent to Three Given $n-1$-Spheres

In this section, the authors consider three oriented $n-1$-spheres, and the goal is to determine the oriented $n-1$-spheres tangent to the three aforementioned oriented $n-1$-spheres. If $n = 2$ (resp. $n = 3$), this problem is known as Apollonius problem (resp. Dupin problem). Using Minkoswki-Lorentz space, the Algorithm 1 permits to resolve these problems.

One can note that all formulas in (1) are linear and force that the $n-1$-spheres to have the same orientation at the tangency points. Formula (2) permits to find the representation of the $n-1$-spheres on Λ^{n+1}.

Each equation given in Formula (1) defines a hyperplane in the Minkoswki-Lorentz space. The dimension of each hyperplane is $n + 1$, and the



Minkowski-Lorentz Spaces Applications: Resolution of Apollonius and Dupin Problems, Fig. 1 Solution of the Apollonius problem in $\mathcal{E}_2$ when all the radius ρ_0, ρ_1, and ρ_2 are nonnegative. The radii of the circles which are solutions of our problem have not the same sign; ρ_a (resp. ρ_b) is nonnegative (resp. nonpositive)

dimension of the set defined by Formula (1) is $n-1$. Using $\mathcal{E}_2$ (resp. $\mathcal{E}_3$), the authors obtain a line (resp. a two-plane), and the intersection between this line and A^{n+1} is two points (resp. a circle for the Lorentz form or a parabola isometric to a line).

Algorithm 1: Solving of Apollonius-Dupin Problems

Input: Three oriented $n-1$-spheres S_0, S_1, and S_2 of $\mathcal{E}_n$, $n \in \{2,3\}$

1. For i in $[\![0, 2]\!]$, computation of the representation σ_i in $L_{n+1,1}$ of the oriented $n-1$-sphere S_i

2. Determination of σ by

$$\begin{cases} \overrightarrow{O_{n+2}\sigma} \cdot \overrightarrow{O_{n+2}\sigma_0} = 1 \\ \overrightarrow{O_{n+2}\sigma} \cdot \overrightarrow{O_{n+2}\sigma_1} = 1 \\ \overrightarrow{O_{n+2}\sigma} \cdot \overrightarrow{O_{n+2}\sigma_2} = 1 \end{cases} \tag{1}$$

and

$$\overrightarrow{O_{n+2}\sigma^2} = 1 \tag{2}$$

3. For i in $[\![0, 2]\!]$, from the solutions σ_s of the equations given by Formulas (1) and (2), computation of tangency points using the light-like vectors $\overrightarrow{\sigma_s\sigma_i}$

4. Computation of the oriented $n-1$-spheres S_s of $\mathcal{E}_n$ from the solutions σ_s of the equations given by Formulas (1) and (2)

Output: A family of oriented $n-1$-spheres tangent (with the same orientation) to S_0, S_1, and S_2

Linear Solving of Apollonius Problem

The Figs. 1 and 2 shows a solution of the Apollonius problem in $\mathcal{E}_2$ with the same geometric circles (Table 1).

In Fig. 1, Formulas (1) and (2) lead to

$$\begin{cases} \sigma_a\left(\dfrac{32\sqrt{6061}-1058}{6975}, \dfrac{12\sqrt{6061}-203}{2325}, \dfrac{-6\sqrt{6061}-286}{2325}, \dfrac{-8\sqrt{6061}-278}{465}\right) \\ \sigma_b\left(\dfrac{-32\sqrt{6061}-1058}{6975}, \dfrac{-12\sqrt{6061}-203}{2325}, \dfrac{6\sqrt{6061}-286}{2325}, \dfrac{8\sqrt{6061}-278}{465}\right) \end{cases}$$

which define the circles C_a and C_b of centers Ω_a and centers Ω_b and of radii ρ_a and ρ_b. The coordinates of Ω_a are

$$\left(\frac{4\sqrt{6061}+1363}{1094}, \frac{-5\sqrt{6061}-473}{547}\right) \simeq (1.53053902924, -1.5763475731)$$

whereas the coordinates of Ω_b are

$$\left(\frac{-4\sqrt{6061}+1363}{1094}, \frac{5\sqrt{6061}-473}{547}\right) \simeq (0.961234279272, -0.1530856993)$$

The radius of C_a is

$$\rho_a = \frac{48\sqrt{6061}+1587}{1094} \simeq 4.86646835086$$

whereas the radius of C_b is

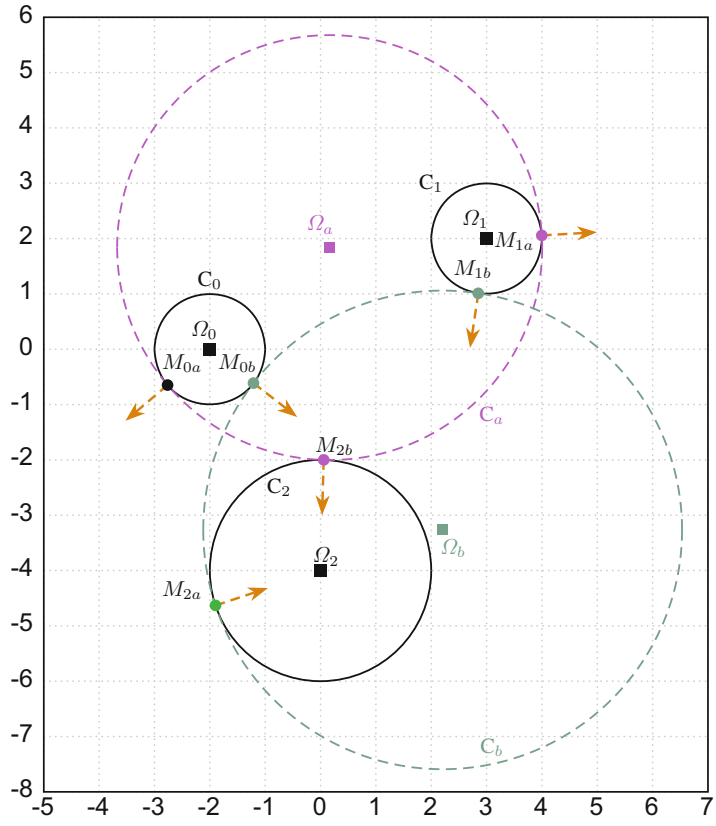
$$\rho_b = \frac{-48\sqrt{6061}+1587}{1094} \simeq -1.96518864336$$

The light-like vectors which define the points of tangency are defined in Table 2.

In the Fig. 1, the radius ρ_2 is changed into its opposite, and the Fig. 2 shows the solution of this new Apollonius problem in $\mathcal{E}_2$.

Formulas (1) and (2) lead to

M



Minkowski-Lorentz Spaces Applications: Resolution of Apollonius and Dupin Problems, Fig. 2 Solution of the Apollonius problem in $\mathcal{E}_2$, the radius ρ_2 used in Fig. 1, is changed into its opposite

$$\begin{cases} \sigma_a\left(\dfrac{32\sqrt{319}+34}{2325}, \dfrac{12\sqrt{319}-181}{775}, \dfrac{-6\sqrt{319}+478}{775}, \dfrac{-8\sqrt{319}-86}{155}\right) \\ \sigma_b\left(\dfrac{-32\sqrt{319}+34}{2325}, \dfrac{-12\sqrt{319}-181}{775}, \dfrac{6\sqrt{319}+478}{775}, \dfrac{8\sqrt{319}-86}{155}\right) \end{cases}$$

which define the circles C_a and C_b of centers Ω_a and centers Ω_b and of radii ρ_a and ρ_b. The coordinates of Ω_a are

$$\left(\frac{-4\sqrt{319}+83}{70}, \frac{\sqrt{319}-5}{7}\right) \simeq (0.165, 1.837)$$

whereas the coordinates of Ω_b are

$$\left(\frac{4\sqrt{319}+83}{70}, \frac{-\sqrt{319}-5}{7}\right) \simeq (2.206, -3.266)$$

The radius of C_a is

$$\rho_a = \frac{16\sqrt{319}-17}{70} \simeq 3.840$$

whereas the radius of C_b is

$$\rho_b = \frac{-16\sqrt{319}-17}{70} \simeq -4.325$$

The light-like vectors which define the points of tangency are defined in Table 3.

$$\rho_a = \frac{-141}{40} \simeq -3.525$$

The light-like vectors which define the points of tangency are given in Table 4. One can note that if the authors change the orientation of the line C_0, the solution is two circles with nonnegative radius. The Dupin problem is now on consideration.

Linear Solving of Dupin Problem

The authors replace the circles given in Table 1 by spheres, and the authors add a zero as last component: the centers of the spheres belong to

the plane of equation $z = 0$ in $\mathcal{E}_3$. The representations of these spheres on Λ^4 are given in Table 1; the expressions on Λ^3 and Λ^4 are the same. The solution of the Dupin problem leads to a cylinder of revolution or a cone of revolution or cubic or quartic surface: the Dupin cyclides (Cayley 1873; Darboux 1887, 1917; Druoton 2013; Druoton et al. 2014; Dupin 1822; Garnier and Bécar 2017; Pratt 1990, 1995). These surfaces are canal surfaces in two ways: the centers of the spheres which define a quartic Dupin cyclide belong to an

(**b**) The three initial spheres S_0, S_1, and S_2, the quartic horned Dupin cyclide, and two characteristic circles

Minkowski-Lorentz Spaces Applications: Resolution of Apollonius and Dupin Problems, Fig. 6 The parabola $\mathcal{P}$ and some circles ($n-1$-spheres) of the one-parameter family $\mathcal{F}$ in $\mathcal{E}_2$, $p=-1$, and $q=5$. These circles have been drawn for the values 0, $\pm\frac{1}{4}$, $\pm\frac{1}{2}$, $\pm\frac{3}{4}$, ± 0.85, ± 0.95, and ± 1 in Formulas (3) and (4)

ellipse and a hyperbola; and the centers of the spheres which define a cubic Dupin cyclide belong to two parabolas. Moreover, each sphere of a family of spheres which generates the Dupin cyclide is tangent to the all spheres of the other family.

The circles computed in Figs. 1, 2, and 3 are called principal circles and permit the determination of Dupin cyclides parameters.

From Fig. 1, the parameters of the quartic ring Dupin cyclide are

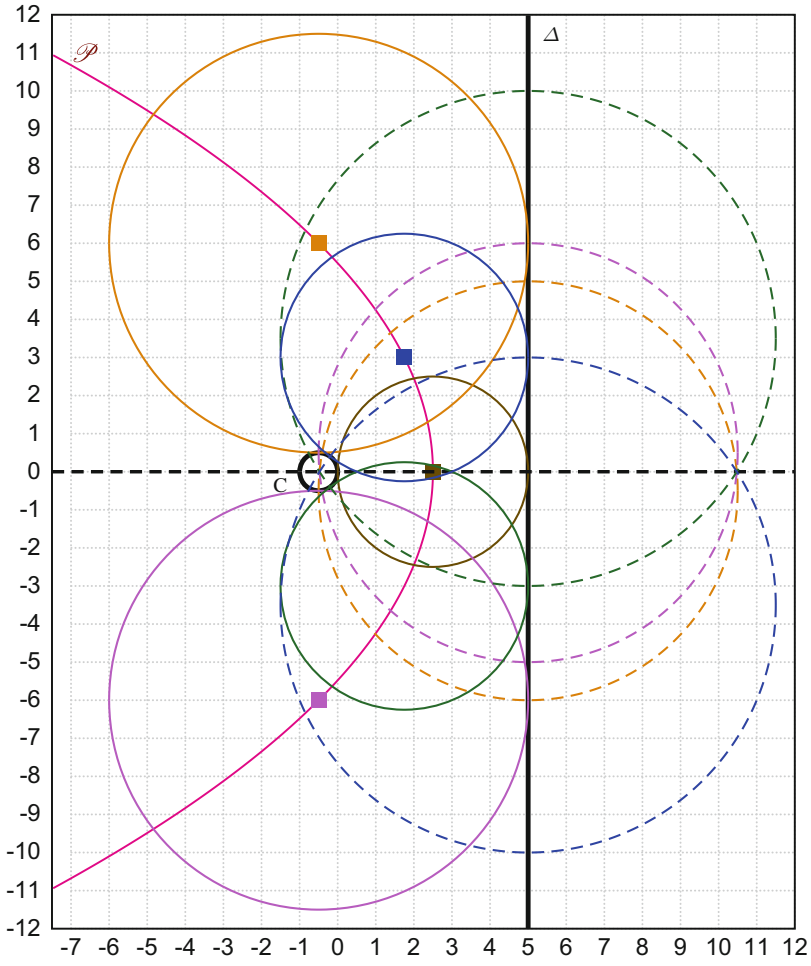
$$(a, c, \mu) \simeq (3.416, 0.766, 1.451)$$

and figure shows the solution of this Dupin problem (Fig. 4).

From Fig. 2, the parameters of the quartic horned Dupin cyclide are

$$(a, c, \mu) \simeq (4.082, 2.748, 0.243)$$

and figure shows the solution of this Dupin problem (Fig. 5).



Minkowski-Lorentz Spaces Applications: Resolution of Apollonius and Dupin Problems, Fig. 7 The parabola $\mathcal{P}$ and some circles ($n-1$-spheres) of the one-parameter family $\mathcal{F}$ and their orthogonal $n-1$-spheres in $\mathcal{E}_2$, $p=-1$ and $q=5$ and the envelope of $\mathcal{F}$ which is the union between a circle C and a line Δ. These circles have been drawn for the values 0, $\pm\frac{1}{2}$, and ± 1 in Formulas (3) and (4)

Family of $n-1$-Spheres Centered onto a Parabola of $\mathcal{E}_n$

Let p et q be two reals such as

$$pq < 0$$

The parabola $\mathcal{P}$ is defined as the set of $\Omega(t)$ defined like this

$$\overrightarrow{O_n\Omega(t)} = \left(\frac{q}{2} + \frac{(p-q)}{2}t^2\right)\overrightarrow{e_1} + (p-q)t\overrightarrow{e_2} \qquad (3)$$

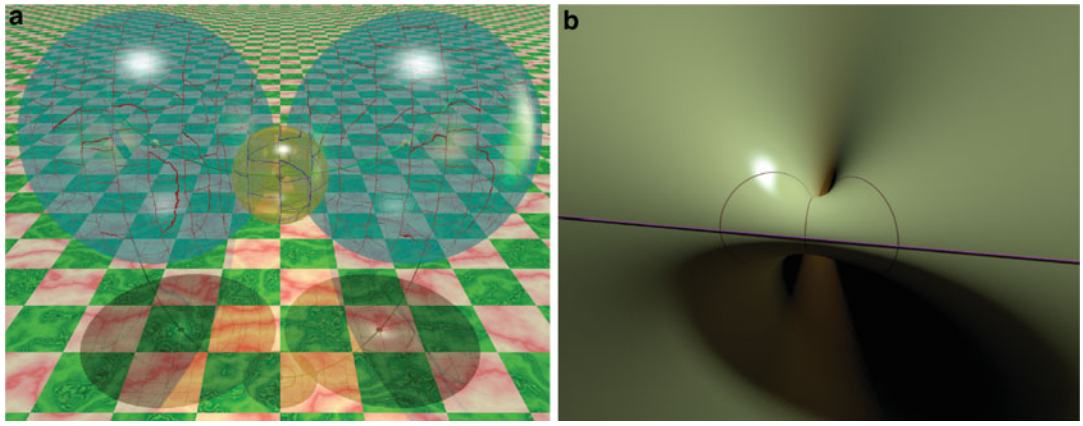
where $t \in \mathbb{R}$.

The one-parameter family $\mathcal{F}$ of oriented n–1-spheres is defined: the centers are $\Omega(t)$, and the radii are

$$\rho(t) = \frac{q-(p-q)t^2}{2}, t \in \mathbb{R} \qquad (4)$$

and the envelope defined by the family $\mathcal{F}$ is computed. Figure 6 shows an example in $\mathcal{E}_2$ with $p=-1$ and $q=5$.

The representation of the family $\mathcal{F}$ in the Minkowski-Lorentz space is



Minkowski-Lorentz Spaces Applications: Resolution of Apollonius and Dupin Problems, Fig. 8 Generation of a cubic Dupin cyclide in $\mathcal{E}_3$. (**a**) The parabola P and three spheres ($n-1$-spheres) of the one-parameter family. (**b**) The cubic Dupin cyclide and three characteristic circles

$$\overrightarrow{O_{n+2}\sigma(t)} = \frac{2}{q-(p-q)t^2}\overrightarrow{e_o} + \frac{t^2p(p-q)}{q-(p-q)t^2}\overrightarrow{e_\infty} + \frac{q+(p-q)t^2}{q-(p-q)t^2}\overrightarrow{e_1} + \frac{2(p-q)t}{q-(p-q)t^2}\overrightarrow{e_2}$$

and the derivative sphere (15) is

$$\overrightarrow{O_{n+2}\,\dot\sigma\,(t)} = \frac{2t(p-q)}{(p-q)^2t^2+q(q-p)}\overrightarrow{e_o} + \frac{pq(p-q)t}{(p-q)^2t^2+q(q-p)}\overrightarrow{e_\infty} + \frac{2t\,q\,(p-q)}{(p-q)^2t^2+q(q-p)}\overrightarrow{e_1} + \frac{(p-q)\,((p-q)t^2+q)}{(p-q)^2t^2+q(q-p)}\overrightarrow{e_2}$$

which generates, it $t \neq 0$, the $n-1$-sphere of center $\dot\Omega(t)$ defined by

$$\overrightarrow{O_n\dot\Omega(t)} = q\overrightarrow{e_1} + \frac{(p-q)t^2+q}{2t}\overrightarrow{e_2}$$

and of radius

$$\dot\rho\,(t) = \frac{\left|(p-q)^2t^2+q(q-p)\right|}{2t(p-q)}$$

and $\dot\sigma\,(0)$ is the representation of the hyperplane defined by the point O_n and the unit normal vector sign $(q(p-q))\,\overrightarrow{e_2}$. Figure 7 shows an example in $\mathcal{E}_2$ with $p=-1$ and $q=5$; the envelope is the circle C and the line Δ.

Figure 8 shows an example in $\mathcal{E}_3$ with $p=-1$ and $q=5$; the canal surface is a cubic Dupin cyclide. Using the construction in the plane of equation $z=0$, the two principal circles which permit the computation of the Dupin cyclide parameter are calculated. Moreover, in this plane, the Figs. 6 and 7 are obtained.

Conclusion

This article presents some applications of the Minkowski-Lorentz space and its interest for computer graphics. In section "*n* – 1-Spheres Tangent to Three Given *n* – 1-Spheres," the representation of spheres in the Minkowski-Lorentz space permits to solve classical geometric problems like Apollonius problems or Dupin problems. First, as the point at infinity is seen as any point, we get a more general solution including spheres and hyperplane. Second, a lot of quadratic computations in the Euclidean space become linear in this space. In section "Family of *n*–1-Spheres

Centered onto a Parabola of $\mathcal{E}_n$," an envelope of a family of oriented circles or spheres is computed.

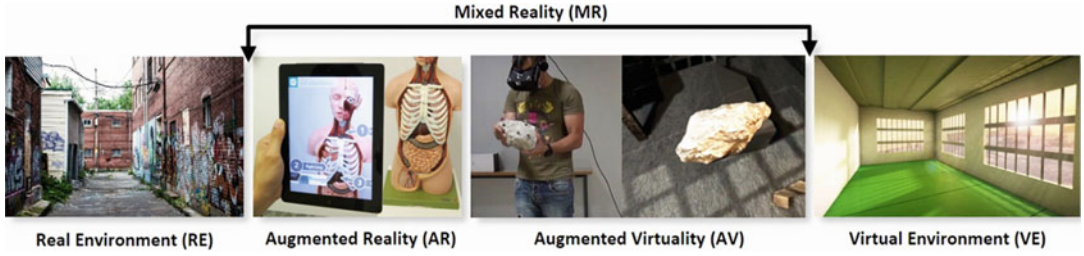
Definitions

The Virtuality Continuum represents a scale which extends from the completely Real



Mixed Reality, Fig. 1 Virtuality continuum

Environment (RE) to the completely Virtual Environment (VE) with Mixed Reality (MR) laying in between. MR refers to environments anywhere between the extremes of the Virtuality Continuum, wherein real world and virtual world objects are presented together in a single display. Augmented Reality (AR) superimposes computer-generated objects upon the RE, while Augmented Virtuality (AV) blends real-world elements into the VE. Virtual Reality (VR) refers to entirely synthetic worlds, which may mimic the physical properties of the real world, wherein the user can be totally immersed.

Introduction

The Virtuality Continuum encompasses all possible variations of blending real and virtual elements into a single environment, with the RE and VE laying at the ends of the scale. MR spans between RE and VE, referring to environments which integrate virtual and physical elements within a coherent space (see Fig. 1), with the two most popular MR paradigms being AR and AV (Milgram and Kishino 1994).

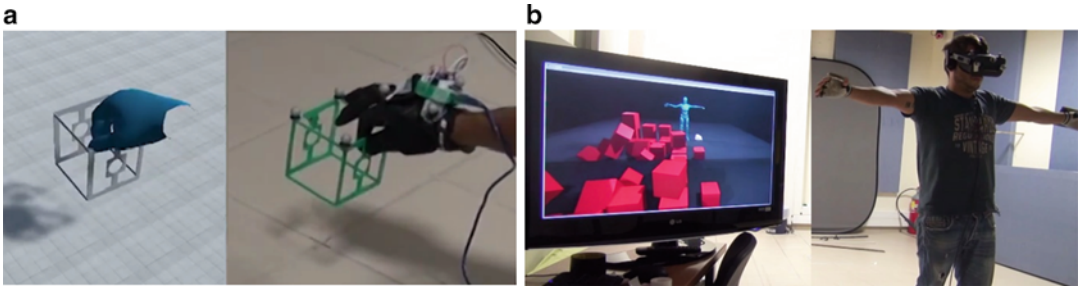
Augmented Reality (AR)

AR applications may be implemented through three different methods. Marker-based AR is based on vision tracking and relies upon the placement of fiducial markers into the RE, which are then tracked via a camera feed, projected onto displays of devices such as smartphones, Head-Mounted Displays (HMDs), or Personal Computers (PC). In marker-based, the RE is streamed through the camera feed and superimposed by virtual elements, based on the location of the fiducial marker (Azuma et al. 2001). Figure 2a shows an example of marker-based AR, using the popular AR development framework Vuforia (https://www.vuforia.com/), where the RE is projected to the user through a web-camera feed and augmented by a 3D model based on the location of a fiducial marker.

Marker-less AR is based on computer vision and motion tracking technology, to accurately place 3D objects on top of the RE which the user sees through the device's camera feed (Azuma et al. 2001). A popular framework for marker-less AR development is ARCore (https://developers.google.com/ar/discover/). ARCore blends virtual objects with the RE, employing (a) motion tracking, to estimate the phone's position and orientation in relation to the world and ensure accurate projection of virtual objects; (b) perception of the environment, to detect the dimensions and positioning of flat horizontal surfaces so as to place virtual objects on them; (c) light estimation, to properly estimate the RE's light conditions, thus overlay the virtual objects upon the RE with appropriate shadows and lighting (see Fig. 2b).

The third method for realizing AR applications is sensor-based AR, wherein multiple commodity sensors are utilized to extract device's rotation and direction. This information allows the appropriate positioning of virtual elements on top of the RE, which the user sees using the camera feed or see-through capability of the device. Typically, sensor-based AR utilizes GPS to acquire user location, providing accurate outdoors positioning with respect to virtual elements, which are often bound to real locations (Zhou et al. 2008). Figure 2c illustrates an example of sensor-based AR with GPS integration, created with the AR

Mixed Reality, Fig. 2 (**a**) Marker-based AR; (**b**) marker-less AR; (**c**) sensor-based AR with GPS integration



Mixed Reality, Fig. 3 (**a**) Using real hands and objects into the VE; (**b**) full body representation into VE using motion capture

application development framework Wikitude (https://www.wikitude.com/), where the RE is superimposed with virtual elements based on the device's rotation, direction, and location.

The outspread of camera- and sensor-enabled smartphones and HMDs has resulted in the establishment of AR as the most widespread type of MR, with numerous applications in a variety of fields, such as gaming, tourism, military, and medicine (Azuma et al. 2001).

Augmented Virtuality (AV)

AV refers to the augmentation of the VE with real elements, aiming at enriching the overall user experience (Schnabel et al. 2007). AV allows users to navigate within a completely synthetic world, enabling interaction with either fictional or real objects (Ternier et al. 2012). AV projects developed in the past are scarce and have mostly focused on embedding real-world camera feeds and a few user movements into the VE (Regenbrecht et al. 2004).

However, recent technological advances, such as data gloves (Silva et al. 2013) and motion capture (Chan et al. 2011), fueled the development of AV worlds, facilitating the integration of real elements into the VE. Figure 3a demonstrates an AV example where a data-glove, powered by Arduino (https://www.arduino.cc/), provides information of the user's finger position and rotation, while the hand's overall position, along with the one of another real object, is tracked using a motion capture system by Vicon (https://www.vicon.com/). This implementation enables concurrent interaction with both real and virtual objects. Figure 3b illustrates another example of AV, wherein the motion capture system by Vicon is integrated with an Oculus Rift (https://www.oculus.com/rift/) HMD to transfer the full body movement of a user from the RE to the VE in real time.

Conclusion

In 1994, Milgram and Kishino foresaw that delimiting AR and AV worlds would be hard, as future technological advances would allow seamless blending between RE and VE (Milgram and Kishino 1994). Their prediction has been confirmed to a certain degree, since the predominance of either RE or VE in recent AR and AV worlds is equivocal. MR remains the most widespread term used to describe the area between RE and VE and represents a particularly promising field of research and commercial exploitation.

Augmented reality; Holography; Immersion; Information visualization; User experience; Virtual reality

Definitions

Mixed reality is related to the hybrid visualization of virtual objects superimposed in real scenarios with the possibility of interaction with them by the users.

Data visualization places the information/data in focus, distinguishing it from the unnecessary

information and facilitating the understanding of correlated data, thus allowing the recognition of patterns and facilitating inferences about different concepts.

Introduction

Currently, the visualization of information and data can be improved by the use of techniques related to the concepts of mixed reality (MR) and immersive user experience. While the MR is related to the merging of real and virtual worlds to produce new environments and visualizations, the immersive user experience refers to the quality that an interaction offers to the user, allowing him/her to feel connected to the system and being part of the presented data visualization.

MR combines characteristics of virtual reality (VR), augmented reality (AR), and holography. The VR deals with the virtual environment interaction, generated by computer, that allow people to visualize, manipulate, and interact with representations of a three-dimensional (3D) scenario and objects in real time. For this, the user interacts with the VR through specific devices such as the head-mounted display (HMD) or VR glasses, in order to improve the feeling of immersion during the interaction (Milgram and Kishino 1994; Burdea and Coiffet 2003; Bowman et al. 2004; Krevelen and Poelman 2010).

The AR, on the other hand, allows the visualization of virtual objects combined with scenes from real environments with mobile devices such as smartphones and tablets or AR glasses and head-mounted display.

So the real and virtual environments are connected, enriching the real world with computer-generated virtual objects or other technological devices that seem to coexist in the same space and run in real time in an interactive way (Azuma 1997; Azuma et al. 2001; Milgram et al. 1994).

Another way of visualizing and interacting with 3D images is through the concept of holography (Leith 1972; Schnars et al. 2015). A hologram is a 3D image obtained from the projection of light on two-dimensional figures.

From such concepts, the MR works with virtual objects (VR) inserted in real scenes (AR) as part of this universe (holography), allowing the direct interaction of the user with virtual objects with or without the use of specific devices for this purpose, such as HMD or VR/AR glasses.

Besides MR, data (or information) visualization is another important emergent technology. Considering which the amount of data in the world is growing faster than ever before, data visualization techniques help people make sense of the data and turn it into insights (Card et al. 1999; Mazza 2009). In this context, the idea of immersive data visualization is to offer full interaction with the data, allowing easier recognition and retention of patterns (Kreylos et al. 2008; Manning et al. 2008; Han et al. 2012; Donalek et al. 2014; Geryk 2015; Olshannikova et al. 2015).

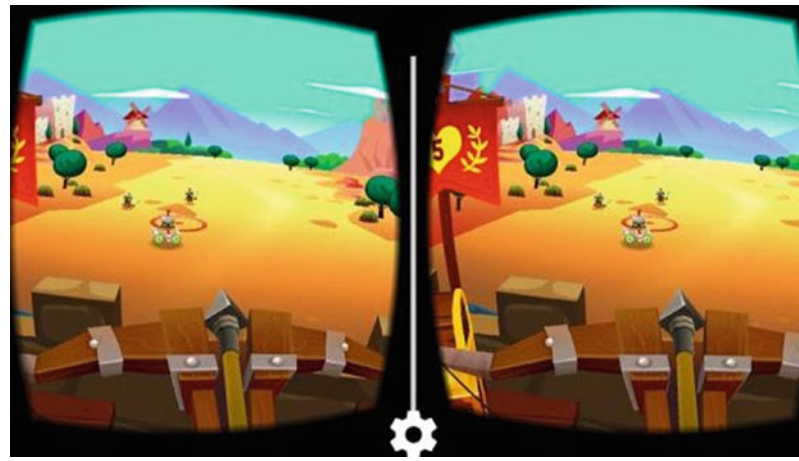
In this context, this article presents and discusses concepts of MR applied to data visualization field in order to improve the analysis by users through an immersive interaction.

Background

According Kim (2005), the VR consists of reproducing a synthetic experience representing a context of virtual simulation to the user. The VR system has three essential components: one or more screens, a set of sensors that detect the movements and stimulate the user, and a mobile device, console, or computer, which controls the whole experience (Fig. 1).

However, one of the major problems of the current VR devices is the motion sickness related to the user's movement in the virtual world and the monitoring of the image displayed on the screen (Hettinger and Riccio 1992). This problem occurs due to the need to generate stereoscopic images (Fig. 2), that is, two scenes being one for each eye in order to produce a high degree of realism in the sensation of depth, which can cause a drop in performance. If the update time is too long, this will cause nausea and/or discomfort.

Mixed Reality and Immersive Data Visualization, Fig. 1 VR glasses with a smartphone inside displaying the video



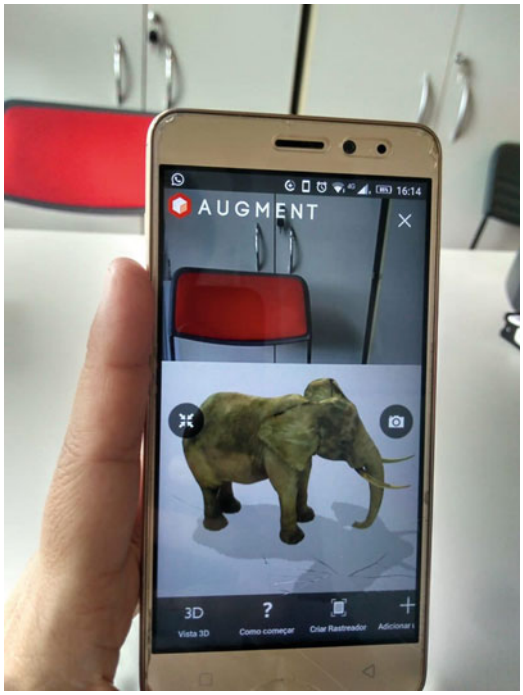
Mixed Reality and Immersive Data Visualization, Fig. 2 VR stereoscopic images from the "Romans From Mars 360" game (Majesco Entertainment 2017)

While VR deals with user immersion in a virtual world, the AR allows the visualization of virtual objects combined with scenes from real environments with mobile devices such as smartphones, tablets, or AR glasses (Fig. 3). AR provides the user an interaction natural and direct with the environment.

Both VR and AR technologies need headwear, eyewear, or mobile device in order to allow the user interaction. The holography, instead, presents the scene or object in real space (floating in midair) without the need for 3D glasses or similar, allowing the viewer to look around objects and see them from a slightly different perspective, as they would in real life. Then, this leads to a more comfortable and naturalistic viewing experience. Examples of techniques for generating holograms include software modeling, particle model, and optical reflection (Collier et al. 1971). Figure 4 presents the optical reflection hologram, a common technique based on a plane screen that reflects the 2D images in a translucent and reflective material in an inverted pyramid format, where the holography forms at its center.

These concepts related to MR are possible to apply to data visualization by promoting such an immersive experience for the user. In this context, visualization is a form of communication that transcends application and technological boundaries because it offers a way to data discovery (Defanti et al. 1989). According to Ware (2008), visualization used to be mental images that people formed while they thought about something, but now the term is related to a graphical representation of some data or concept.

The immersive data visualization should allow the user to analyze the dataset and/or information in order to identify patterns growing, which may be indicative of trends, and the discovery and extraction of new, useful, and interesting knowledge from databases (mainly nonconventional databases) (Marr 2017).



Mixed Reality and Immersive Data Visualization, Fig. 3 AR example of a 3D virtual elephant projected over a real scene generated with Augmented software (Augmented 2018)

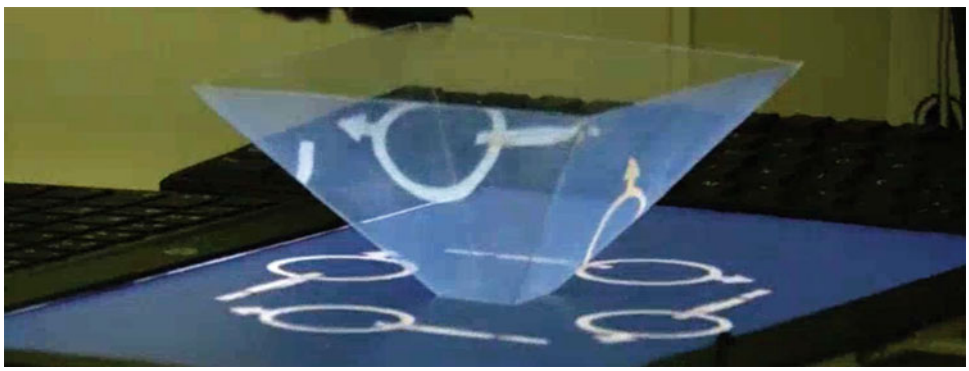
The next section discusses the contribution of the concepts related to MR in order to extract value from the data by increasing the user understanding and improving decision-making capability through immersive interaction.

Data Visualization and Immersive User Experience with Mixed Reality

Bowman and McMahan (2007) already affirmed that the goal of immersive virtual environments was to let the user experience a computer-generated world as if it were real, producing a sense of presence, or "being there," in the user's mind. According to Lemoine et al. (2003), the success of applications involving virtual elements depends on the degree of immersion, comfort, and the nature of the interaction.

Therefore, in MR, the user has the ability to explore the virtual environment and the real world at the same time. The MR combines characteristics of VR with AR through the insertion of virtual objects in the real world and allowing the immersive interaction of the user with such objects, producing new environments in which physical and virtual items coexist and interact in real time (Fig. 5).

There are three basic ideas involving MR and the user experience: (1) immersion, related to the feeling of being inside environments; (2) interaction, which corresponds to the ability of the user to instantly modify the virtual objects projected in



Mixed Reality and Immersive Data Visualization, Fig. 4 3D hologram obtained from a video (Hologram Project by Kiste 2014) of 2D images projected over a translucent and reflective material in pyramid format

Mixed Reality and Immersive Data Visualization, Fig. 5 MR generated with Linq mixed-reality headset (Stereolabs 2017; Steele 2016)

the real world through actions on these; and (3) involvement that is the degree of user motivation with certain activity. These concepts can aid the analysis of data, since they amplify the process of insight, transforming the data and/or amplifying the data as images (Card et al. 1999; Spence 2007).

When an image is analyzed, a cognitive process begins and perceptual mechanisms are activated to identify patterns and segment elements. The correct mapping of data to visualization is crucial, since one can discard relevant information or exceed the amount of irrelevant information (Ware 2004, 2008). Thus, the image should limit the amount of information that the user receives while keeping him/her aware of the total information space and reducing the cognitive effort (Ward et al. 2015; Silva 2017).

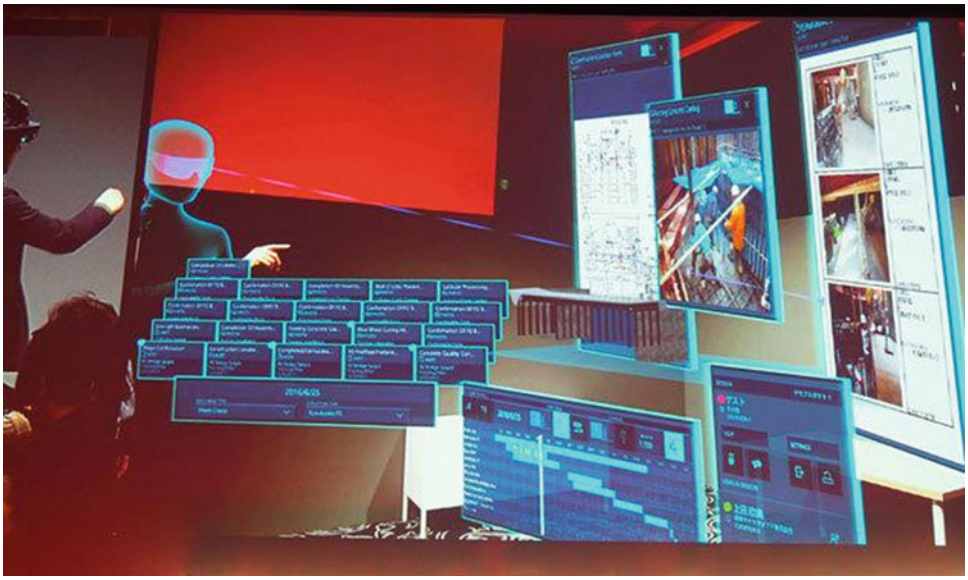
Regarding the common visualization techniques, there are two main problems: defining which visual structures should be used to represent the data and defining the location of such visual structures in the display area (Silva 2017). These problems involve the proposition of adequate visual structures with visual attributes and their location, and reaching a solution involves responding to the following questions:

- What is the problem?
- What is the nature of the data?
- How many dimensions are involved?
- What are the data structures?
- What kind of interaction is required?

Moreover, the classical Shneiderman's visual information-seeking "mantra" (Shneiderman 1996) gives more directions about important features in a visualization: "First, overview, then, zoom and filtering, and finally, details on demand."

Graphs are the most intuitive form of data visualization by their both hierarchical and relational characteristics. An interactive graph or tree solves part of the problem, allowing the user to highlight the information in focus through selection, but the overlapping edges are still a problem. Moreover, as the dataset grows, incorporating new concepts (and their relationships) increases the visualization complexity. Although one can add interaction to solve part of the problem, allowing the user to select the information he/she wants to put into focus, overlapping edges remain a problem.

Besides, data representation in a three-dimensional (3D) space allows the user to navigate through in-depth visual representations, rotating, expanding, and selecting the desired items. However, 3D charts on flat screen can make information difficult to understand and



Mixed Reality and Immersive Data Visualization, Fig. 6 3D hologram obtained from "Holostruction" project generated with HoloLens (Microsoft Asia News Center 2017; Microsoft HoloLens 2017)

compare because these views require the user immersion and depth perception.

In this context, stereo visualization improves user immersion through perception related to the shapes and proportions. The natural interaction with data enhances the intuitive user experience from an extra dimension of information. According Marr (2017), by presenting data that wraps around the user, more than the traditional 3D become available. As well as placement on X, Y, or Z coordinates, data points can be distinguished by size, color, transparency, as well as direction and velocity of movement.

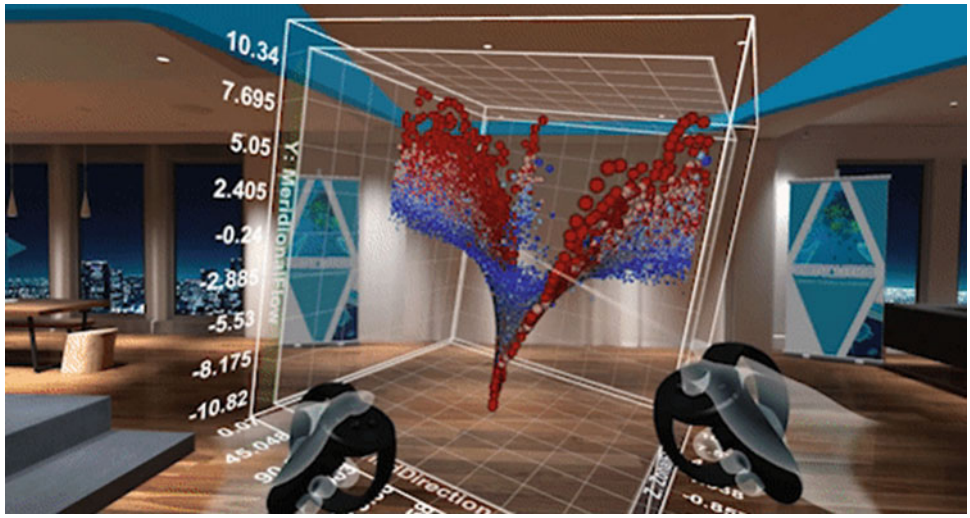
Figure 6 presents an image that applies MR to data visualization through the exhibition of interactive overlaying holograms and enables the user to view and manipulate these within a visible, real-world context.

In relation to data analytics visualization, if the MR techniques are combined with visual analytics, it is possible to amplify the cognition and reduce exploration time of a dataset, allowing the recognition of patterns and facilitating inferences about different concepts. MR and visual analytics can improve both quality and efficiency of data visualization systems, providing semiautomatic means for driving the visual exploration in a immersive way and replacing traditional 2D charts by interactive and immersive 3D colorful visualizations where the user can "dive into" data and see patterns that are not discernible on 2D charts.

Figure 7 presents an image from the Virtualitics (Donalek 2017), an immersive and collaborative data exploration platform that merges artificial intelligence, big data, and MR. In this image, it is possible to visualize a collaborative and customizable shared space to analyze data, build virtual dashboards, and present and discuss insights.

Besides data visualization and analysis, the possibilities of MR applications are extensive as, for example, military drills based on MR will give the army capabilities beyond what the human being possesses today (Fig. 8). They will be able to view information in real time, share it with other comrades, if necessary share their field of vision, add virtual objects to the training combat field, etc.

Education, health, arts and entertainment, architecture and design, and security are areas that will also benefit from MR technology applied to data visualization.



Mixed Reality and Immersive Data Visualization, Fig. 7 3D dashboard of Virtualitics Immersive Platform (Donalek 2017)

Mixed Reality and Immersive Data Visualization, Fig. 8 3D visualization simulations of a Royal Australian Air Force (RAAF) and Department of Defense project that uses HoloLens (Odom 2017)

Conclusion

Over the last decade, there has been a steady increase of data made available in several forms, and efficient methods for data visualization and interaction became necessary in order to facilitate the comprehension of domains represented in diverse systems.

However, it is not simple to create a visualization and interaction that displays effectively all

the information and, at the same time, allows the user to easily perform various operations on the dataset. The MR technology can contribute to these aspects once it replicates and extends natural and physical interaction through advanced interfaces.

MR combines concepts of VR, AR, and holography to promote innovation and improve the user experience in the interaction of these with graphical representations. This is possible due to advances in techniques of computer vision, graphic processing, and rendering, among others. MR applied to data visualization allows an immersive and approximate real-world experience to the user in order to make it difficult to distinguish physical reality from virtual reality.

Synonyms

Augmented reality; Cultural heritage; Gamification; Holographic augmented reality; Mixed reality; Storytelling; Virtual reality

Definition

Mixed reality as display technology, gamification as motivational element, and storytelling as interaction metaphor while maintaining the feeling of

presence are identified as key elements for defining the next generation of virtual museums.

Introduction

Storytelling, presence, and gamification are three basic fields that need to be taken into account when developing novel mixed reality applications for cultural heritage, based on the recent renaissance of commercial VR and AR hardware. This survey aims to cover a gap in the bibliography and the last relevant surveys of Papagiannakis et al. (2008), Jung et al. (2011), Foni et al. (2010), and Anderson et al. (2009) which are more than 7 years old, whereas some of these topics are mentioned in several different chapters within Ioannides et al. (2017) but not in single, comparative study. Section "The Role of Storytelling in Cultural Heritage" of this survey covers the state of the art in storytelling for cultural heritage and virtual museums, section "The Role of Presence in Cultural Heritage" the role of presence, and section "The Role of Gamification in Cultural Heritage" the usage of gamification principles. In the last section "Survey of Recent MR Methods for Virtual Museums," a comparison among latest methods in the above areas is presented.

The Role of Storytelling in Cultural Heritage

Storytelling in Museums

Museums have realized the value of storytelling the second half of the twentieth century. Nowadays museums find themselves competing with the large offer of cultural products coming not only from the cultural sector but also from the entertainment industry. Therefore, museums need to differentiate and make their products more appealing and attractive to a variety of audiences. Influenced by the "new museology" concept and the transformation of the museological practice, which refers to a shift in the social roles of museums encouraging new styles of communication and expression, in contrast to the "cultural authority" of museums based on classic, collections-centered models, museums have changed.

Museums can act as primus inter pares (first among equals) and create a direct communication with the visitors, in which museum is the communicator and the visitor is the receiver and vice versa, providing the visitor the opportunity to actively participate in the story. Museums can have a conversation with the visitor, which can share her/his experiences and personal views. To this end, recent AR/VR commercial h/w technological advances enable the use of sophisticated tools to deliver virtual museum stories and information in a number of ways for experience enhancement, knowledge construction, and meaning making (Sylaiou et al. 2009).

Storytelling Using AR and MR (Merging AMI Installations with Mobile Devices and Physical Artifacts Through Stories)

Storytelling in Mixed Reality

Static visualizations have been traditionally employed to support storytelling in the form of text, diagrams, and images. The adoption of dynamic approaches utilizing state-of-the-art 2D and 3D graphics is emerging in an effort to explore the full potential of interactive narration. Rather than simply constituting an additional layer to exhibitions, the enhancement of CH institutions through interactive MR exhibits added value to the overall user experience (Marshall et al. 2016), especially if combined with personalization to each user's interests (Partarakis et al. 2016). Interactive storytelling in MR environments bridges digital and physical information, augmenting the real world and offering interaction which corresponds to the user's actions in the physical space. Storytelling can be employed for associating tangible and intangible information; such an example is Huang and Huang (2013), where the authors compound information for the promotion of indigenous cultural heritage.

Storytelling Authoring

Authoring refers to the process of creating narrations that form a digital story. In terms of authoring, the most common story types are

character-based stories (Cavazza et al. 2002), linear timeline-based stories (Bimber et al. 2003; Drossis et al. 2013b), and ontology-based stories (Casillo et al. 2016). In terms of authoring virtual worlds, Lu et al. (2008) present an editing environment for facilitating the construction of 3D museums. Additionally, narratives description and structuring is also performed using authoring tools. Ardito et al. (2017) create a similar tool for storytelling creation and customization, focusing on the aspects of smart objects integrated in CH installations. Modern cameras are equipped with depth sensing capabilities allowing the real-time scanning of surroundings with sufficient detail. Such cameras are increasingly being adopted by consumer smartphones, such as the Google Tango compatible devices (Klingensmith et al. 2015). Therefore, such approaches can facilitate augmented reality environment rapid prototyping and authoring in a straightforward manner without requiring user expertise on computer science.

The Role of Presence in Cultural Heritage

"Presence" refers to the phenomenon of people behaving and feeling as if they "are there" in the virtual world created by computer displays (Ioannides et al. 2017). It is an incredibly powerful sensation, which is unique to MR, as it is not possible to recreate it in any other medium.

The Role of Illumination in MR Presence for Cultural Heritage

Introduction

There are two key components that are necessary in order to achieve the right illumination and thereby a high sense of presence in a MR cultural heritage environment: *authentic appearance of the light* and the *correct dynamic range*. Prior to the introduction of electricity, past societies relied entirely on daylight and lighting from flames for illumination. Any MR cultural heritage environment which is lit by modern lighting would thus not be authentic. In addition, the real world contains a wide range of lighting conditions, from dark shadows to bright sunshine. The MR environment needs to recreate this dynamic range of a scene. Where this is not possible using existing technology, techniques such as tone mapping need to be used.

High-Dynamic-Range (HDR) Environments

The dynamic range in a scene is defined as the ratio between the darkest part of the scene and the brightest. While the human visual system is able to adapt to the full range of light in a scene, traditional (also known as low-dynamic-range (LDR)) imaging is not able to capture or display a dynamic range of more than 256 to 1 (8 stops). High-dynamic-range (HDR) imaging, on the other hand, by using 32 bit IEEE floating point values to represent each color channel, can capture and display all the visual data in a scene. Failure to capture the full range of visual data can lead to important information being missed due to under- or overexposed regions in the image. Even if a scene has been captured, or created in HDR, detail can still be lost when the image is subsequently displayed on a device which is not HDR. In such a case, the HDR images need to be tone mapped in order to attempt to preserve the perception of the real scene on the LDR device. Many tone mapping operators (TMOs) have been presented over the years. More recently new TMOs have needed to be developed specifically for displaying 360° HDR images on head-mounted displays (HMDs) which are not yet HDR display devices. This is because the lighting in a full environment can vary significantly depending where the person is looking. HDR imaging is especially important in MR environments to ensure the virtual objects are relit with the same levels of lighting as in the real scene. As such, HDR is increasingly being been used within CH applications to improve their authenticity.

The Impact of Virtual Narrators to Presence in Virtual Museums

One of the important aspects which enhance the feeling of presence in CH (Papaefthymiou and Papagiannakis 2017) is the interaction with and behavior of the virtual narrators. These narrators should have humanlike behaviors, so that the visitors will feel like the virtual narrator that is

speaking to them is real and that he/she is in the same room with them. An issue that rises at this point is how a virtual narrator can be as realistic as possible, with humanlike behavior and characteristics. For a virtual character to look as real as possible, it is not enough just to create him/her programmatically with code. It would be more realistic if that character could be reconstructed out of a real human. That way, the appearance of the character would resemble the appearance of the real person based on whom this character was reconstructed. This can be realized by scanning a real person with the Occipital™ depth sensor, specially designed for this task. The photogrammetric method is one of the best methods yet to reconstruct the texture of a real person. By scanning the person with the special sensor mentioned before and applying the texture, a 3D model of that person can be created. That way, a 3D model of a real person will be able to be used in computer graphics and mixed reality applications, in order to tell a story and communicate with the people that will use the specific mixed reality application, as shown in Figs. 1 and 2 (Papaefthymiou and Papagiannakis 2017).

Mobile AR Interactive Applications for Virtual Museums

Mobile augmented reality systems (MARs) are increasingly currently being tested in rich content heritage environments by both creative professionals and laymen. Recent mobile hardware such as GPU-enhanced, multicore smartphones and novel untethered AR headsets (e.g., HoloLens by Microsoft) pave the way for a new breed of AR services and applications; however there are a number of issues to consider which regard the aspects of information presentation and physical interaction (Papaefthymiou and Papagiannakis 2017; Papagiannakis 2017; Ioannides et al. 2017; Kateros et al. 2015; Li and Duh 2013). With respect to direct hand interaction, there are limitations in handheld devices where the free hand is used for interaction with the 3D objects (e.g., small screen size, unsuitability of point and click gestures for manipulation, finger occlusion), whereas in HMDs hands are an intuitive input channel although bimanual interaction cannot ensure better performance than single-hand interaction, and it is important to optimally assign functions to two hands. For example, in recently

Mixed Reality, Gamified Presence, and Storytelling for Virtual Museums, Fig. 1 The hologram of the priest of the Asinou Church and the viewer interacting via gestures through Microsoft HoloLens, in the ITN-DCH project (Papaefthymiou and Papagiannakis 2017)

Mixed Reality, Gamified Presence, and Storytelling for Virtual Museums, Fig. 2 Digitization of the priest of Asinou Church (to reconstruct his 3D model as a virtual narrator) using the Structure Sensor (Papaefthymiou and Papagiannakis 2017)

introduced ARKit by Apple, which represents a commercial tipping point in terms of mass-market adoption of AR technology, interactions are kept simple with object's movements restricted on a plane, and the possibility of recognition of conflicting gestures. On the HMD side Microsoft HoloLens, although it has promised a hands-free experience, interaction can be frustrating given the limited field of view and the misreading of gestures. Although the promise of MARs is turning into reality, the technical challenges with respect to computational efficiency, information retrieval from different data sources, markerless detection, and hand gesture recognition performance still affect the overall user experience when interacting with MARs.

Immersive Experiences for Interaction with Cultural Heritage

Mixed Reality Installations

Mixed reality has the potential not only to increase motivation to learn but also to raise interest on CH. Thus, CH institutions can increase their appeal and enhance visitor engagement through interactive installations that include public displays (Partarakis et al. 2017). In addition to improving the aesthetic experience, mixed reality environments have influence on visitor experience, thus favoring the probability of revisiting a specific attraction (Jung et al. 2016). Apart from providing an enjoyable experience, mixed reality installations can facilitate cultural awareness, historical reconstruction, and heritage awareness. State-of-the-art approaches are not limited to installations in indoor spaces (Grammenos et al. 2012), but can also involve vehicles that act as portable kiosks (Zidianakis et al. 2016).

Setups and Interaction

Interactive installations in public spaces such as in CH institutions have certain requirements in terms of interaction and setup. The installations need to adapt to fit to the space available, provide content which interests both domain experts and non-expert users, and also present thorough information on demand (Mortara et al. 2014). At the same time, the system design should provide information immediately and support straightforward interaction techniques. Multiuser interaction with public displays is an open issue and constitutes an active area of research. Once people approach the interactive display, they decide their actions with regard to the system. Especially in the context of MR applications, the establishment of interaction with a public display involves transitioning from implicit to explicit interaction (Vogel and Balakrishnan 2004) as the users become engaged to the pervasive display.

Tangible interaction is a form of interaction with mixed reality installations in which physical items act as mediators between the users and the

environment. One aspect of tangible interaction refers to physical objects, which are simply the medium of communicating information. For instance, physical paper is employed as a portable display, augmenting maps or glass-protected models (Grammenos et al. 2011). Interactive maps (Margetis et al. 2017) are a mixed reality application, where printed maps are augmented with additional multimedia information. Furthermore, tangible interaction can involve objects which have meaningful substance with a semantic meaning, such as smart objects (i.e., physical items equipped with sensors such as RFID tags). Smart objects can facilitate related information in its context of use (Petrelli et al. 2016).

Bridging Worlds: Combining AR, MR, and VR

Digital cultural heritage content is combined with physical 3D replicas (Bugalia et al. 2016) in order to provide a virtual tour in architectural sites using MR. This approach has the advantage of moving in a wall-projected 3D virtual environment while placing a physical model in front of the users to act as a minimap assisting navigation. Head-mounted displays are employed in the context of CH foundations for holographic AR and additionally support VR visualizations (Pedersen et al. 2017). VR can act as a medium to visualize CH exhibits otherwise unavailable to users as well as reenactments of historical events offering hands-on experience regarding unattainable content. Such indicative examples of VR usage are elements which are under conservation or even stolen (The Museum of Stolen Art 2017) and such as the battle of Thermopylae (Christopoulos et al. 2011), respectively. A different approach for mixing realities involves using tangible objects as souvenirs which summarize narratives as they were presented to users (Petrelli et al. 2017), acting as personalized keepsakes of their visit in CH institutions. Finally, an interesting approach at Geevor Tin Mine Museum (Jung et al. 2017) combines AR, VR, and 3D printed objects with the common goal of adding value to the overall user experience. The technologies are employed for enriching visits (AR), providing access to inaccessible areas (VR), and souvenirs which the users can keep, respectively (3D printing).

The Role of Gamification in Cultural Heritage

Gamification has been applied to a number of application domains including CH, and it is a popular approach to increase the entertainment and thus the motivation factor of users (Vassileva 2012). It is different from computer games even if it shares a lot of common theories and practices of development. It is considered to be one of the more recent developments of computer game design principles that have been researched since their appearance (Liarokapis et al. 2017a). A major objective of gamification is the improvement of users' engagement that can provide positive effects, but the effects are heavily dependent on personalization (Hamari et al. 2014). Recently, an interactive tool called PhotoTrip was presented that can autonomously recommend CH locations along travel itineraries (Bujari et al. 2017). The application can identify these points of interest by gathering pictures and related information from social media and then provide suggestions and recommendations.

Gamification elements also exist in a number of simulations ranging from serious games to virtual and augmented reality. Similarly, edutainment and gamification are argued to be common recurring themes in the fields of education and cultural communication (Mancuso et al. 2017). In terms of virtual reality, gamification elements were recently shown in a kinesthetic application of sculpturing Cycladic figurines (Koutsabasis and Vosinakis 2017). The user takes the role of an ancient craftsman who creates a figurine with bare hand in a virtual reality environment. In another study, an immersive virtual underwater environment was developed to explore Mazotos shipwreck site and get relevant information about it and its contents (Liarokapis et al. 2017b).

In the following sections, key recent MR projects with rich gamification elements are presented.

Playful Interaction with Cultural Heritage Exhibits (Improved UX)

Immersion is based on covering physically a person's stimuli, namely, vision, spatialized sound,

and haptic feedback (Bowman and McMahan 2007). Haptic feedback (Ott et al. 2007) is examined in literature as an additional means of enhancing immersion. Kosmalla et al. (2017) combine tactile feedback from physical worlds with a virtual rock climbing environment in combination with full body movement and exertion. Immersion is also strongly related to the interaction process: in addition to perceiving a mixed reality (MR) application with human senses, the interaction modality employed constitutes a decisive factor in feeling of immersion and the overall user experience. Contrary to mission-critical domains such as a working environment, CH applications belong to a field in which users are more open to novel alternate interaction modalities. Requirements such as precision and efficiency are not fundamental in such a context, as users may be willing to sacrifice precision and overrule tiredness for entertainment and playful user experience (Drossis et al. 2013a). Playfulness encourages exploration, fosters creativity, and stimulates social interaction by entertaining users and allowing them to escape from the reality (Tsekleves and Darby 2017). Playful interaction is employed for attracting users toward public installations and therefore facilitating user engagement (Williamson and Sundén 2015).

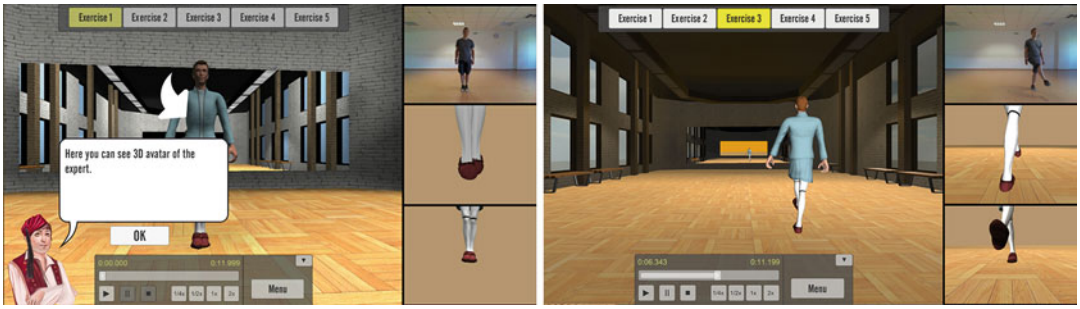
Re-Play: A Cultural Heritage Project that Allows to Replay Ancient Games

In Europe only, there are over 3000 Traditional Sports and Games (TSG). The EU project Re-Play has focused on two families of TSG (Gaelic and Basque) that are integral to the fabric of their communities of origin and have successfully staved off this trend of convergence. The group at MIRALab, University of Geneva, has focused on the development of a realistic real-time animation and rendering platform that enabled the visualization of the virtual national sports heroes as well as the visualization of avatars representing the local heroes (Tisserand et al. 2017). This state-of-the-art animation-rendering system includes dynamic muscle effects, which are modeled over the skin using a novel GPU approach. Based on existing MRI datasets and accurate reconstructed 3D models, the Re-Play platform computes the displacement map and assigns weights to each coordinate in the displacement map based on EMG measurements. To increase the feeling of immersion, photo-realistic 3D models acquired using a 3D scanner have been employed to animate and render the virtual sports heroes.

Gamification Applications for Folklore Dance

Intangible cultural heritage (ICH) includes fragile expressions mainly transmitted orally or by gestures from one generation to the next. In order to support the learning and transmission of ICH expressions, gamification can also be used. Based on the theory of "experiential learning" (Kolb, D.A., 1984, Experiential learning: Experience as the source of learning and development, Englewood.), one of the main pillars of game-based learning, the acquisition of learning is achieved by observing, reflecting, mentally representing, and enacting movements. In accordance with this theory, within the i-Treasures (Dimitropoulos et al. 2018) project, a number of game-like applications for sensorimotor learning of specific dance types and other activities involving full body gestures were designed and developed to support the learning and transmission of a number of ICH expressions. Specifically, a serious game application for transmitting ICH knowledge concerning the Greek traditional dance "Tsamiko" was developed (Kitsikidis et al. 2015) and shown in the figure below. The game was structured as a set of activities, aiming to teach different variations of the dance allowing users to learn by either observing experts' prerecorded movements in the Observe mode or by starting practicing the dance step sequences respectively in the Practice mode (Fig. 3).

During the Practice mode the learner is expected to imitate the moves of the expert avatar displayed on the screen. The addition of a virtual tutor to correct/manipulate/guide the user by providing visual and audio feedback was also supported in order to encourage the learners' "participation" and engagement.



Mixed Reality, Gamified Presence, and Storytelling for Virtual Museums, Fig. 3 Observe and Practice screen of Tsamiko's gamified application within the i-Treasures EU project (Kitsikidis et al. 2015)

Survey of Recent MR Methods for Virtual Museums

In Table 1, a summary of key papers in the last 7 years, after the last relevant survey paper from Anderson et al. (2009), is presented. Although there is no specific MR method that features gamified storytelling with heightened interaction that still maintains full immersion and the feeling of presence, several conclusions and recommendations for next lines of research can be drawn and summarized.

The MR technologies that are used in the key papers (located in Table 1) contribute to the preservation of cultural heritage, each one with its own level of storytelling, presence, gamification, interaction, and tracking methods. Since all of the installations below are MR applications, many of them take into account the gamification field, in order for those applications to be interesting and fun for the viewers. Some of them include storytelling elements (e.g., Papaefthymiou and Papagiannakis 2017; Pedersen et al. 2017), which are used to inform the viewers about the story of a monument, for instance, thus contributing in cultural heritage curation. Furthermore, it can be noted that most of the MR methods below support partial immersion and few of them support full immersion. The term "immersion" is included in purpose as it can be easily quantified based on the display, whereas "presence" is elusive and depends on many parameters and thus difficult to provide that holds true throughout a simulation. VR HMDs thus support full immersion, whereas AR and holographic AR support partial one. Moreover, some applications that run tethered with a computer and do not support VR or AR provided no immersion at all. The majority of these key papers use mobile AR or holographic AR, and that explains the majority of the partial immersion entries on Table 1. A recommendation at this point would be that there should be more MR applications that support desktop or mobile VR with full immersion, as it creates a more realistic experience for the viewers because they do not have access to the real world and the feeling of presence is respectably higher than it is with partial immersion. These technologies can also be categorized in two additional categories, tethered and untethered, according to if an installation needs to be connected to a PC or not (standalone device), respectively. An example of an untethered MR technology, which can be found in the table below, is the Papaefthymiou and Papagiannakis (2017), which uses the Apple iPad Pro device in order to run. It uses Apple's ARKit for camera tracking. The viewers' movements are not limited by cables (since no cables are used), which enhances the feeling of presence as their movements would not be limited if they were exploring the real monument. Also, gamification and storytelling elements are supported, and along with the feeling of presence and freedom of movements, all those elements create the perfect experience for the viewers. Another version of this work runs on the Microsoft HoloLens holographic AR HMD, which is also an example of untethered AR.

On the other hand, there are some great MR applications (e.g., Pedersen et al. 2017; Drossis

Mixed Reality, Gamified Presence, and Storytelling for Virtual Museums, Table 1 Comparison of recent MR methods for virtual museums

Mixed reality method	MR installation	Gamification	Storytelling	Interaction	Tracking	Immersion	Intangible heritage

Tisserand et al. (2017)	Computer with Kinect Sensor for traditional sports preservation	x		Movement	Kinect Sensor	Partial	Yes

et al. 2015; Tisserand et al. 2017), which support gamification and/or storytelling elements, but they limit the movements of the viewers due to the existence of cables or need of a connection with a desktop PC. Although these applications are impressive and greatly contribute to cultural heritage preservation, they restrict the freedom of movement to the users, which in some cases may disrupt the feeling of presence. Based on this discussion, it is recommended for MR applications to be able to run in MR installations that do not restrain the movements of the viewers in any way. Without restriction of movements and with full immersion, the experience of a viewer will reach very high levels. Finally, SpatialStories (Foni et al. 2010), a very recent commercial effort, is a toolset for real-time interactive VR/AR experiences featuring storytelling for non-programmers. Although it has not yet been fully tested, from information gathered from their website, its manual, and its videos, it poses a promising commercial solution in contributing to MR cultural heritage applications.

Conclusions

In conclusion, the ability to innovate in the field of MR gamified storytelling while maintaining presence in the virtual museums of the future will be directly related to the ability to find synergies between the above fields of knowledge, without forgetting that new technologies can play a transcendental role in this equation. And as the quintessential reductive machine, MR technologies are employed as the device that will restore its unity through multiplicity and fragmentation. Hence this work needs to be considered as a further step toward reconciliation and a renewed mutual beneficial relationship between humanities, social sciences, and computer science.

Definitions

Mobile cloud gaming (MCG) is a new type of mobile gaming, in which games are stored, synchronized, and rendered in the remote cloud platform and delivered to mobile users using video streaming technology.

Introduction

As a killer application in the mobile app market, the growth of mobile gaming is very impressive in the past decade. The major obstacle that may hinder the further growth of mobile gaming is the constraint of limited resources on mobile devices. However, it is fortunate that recent advances in cloud computing shed lights on the feasibility of playing high-end video games on mobile devices.

Mobile cloud gaming (MCG) enables mobile users to play games in the cloud and thus mitigates the tension between high requirements of video games and limited resources on mobile devices. By offloading computation-intensive tasks to the powerful cloud platform, the capacity of mobile

devices can be significantly augmented (Wei Cai et al. 2013; Zhang et al. 2013; Wen et al. 2014).

Unlike traditional mobile gaming, mobile cloud gaming offers many novel features: *Firstly*, with mobile cloud gaming, there is no need for mobile users to constantly upgrade their mobile devices; *secondly*, mobile users are allowed to start game playing instantly, without downloading and installing mobile game apps; *thirdly*, mobile games can be platform-independent under the mode of mobile cloud gaming. There is no need for game developers to build a separate game app for each mobile platform (e.g., iOS, Android).

Technical Challenges and Problems

Compared to common cloud gaming, the features of mobile devices pose some additional challenges for mobile cloud gaming. The main challenges of delivering MCG services to mobile devices include the following aspects:

1. *Heterogeneity of Mobile Devices*: There exists significant diversity among hardware configurations of mobile devices (including screen size, resolution, bandwidth, and CPU/GPU). The MCG service provider should consider the heterogeneity of mobile devices when delivering video game streams to mobile devices.
2. *Diversity of Mobile Games*: Different game genres have different QoE (Quality of Experience) requirements. For example, a slight increase of interaction delay is intolerable for the first-person shooter (FPS) games, while it may not be observable for the war strategy games. Therefore, the decision on MCG resource provisioning should consider the difference on QoE requirements among different game genres.
3. *Unreliable Wireless Transmission*: The mobile devices are connected with the MCG platform via wireless channels. However, the conditions of wireless channels are intrinsically unreliable and vary with time. It makes the transmission of video game streams easy to violate the strict latency requirements. Due to the stochastic nature of wireless channels, it is necessary to ensure that game video streaming can adapt to the changes of wireless network conditions.
4. *Limited Battery Life*: In addition to providing sufficiently short latency for real-time gaming and reacting to user inputs timely, it is necessary to take energy efficiency of mobile devices into account. It is critical to reduce energy consumption of computation, communication, and display for mobile cloud gaming.

The above challenges raise a number of questions that should be addressed. Among them, the first critical question is how to better evaluate the QoE of mobile gamers. Only when the QoE target is clear can the MCG service provider know how to provision and configure its cloud resources in a reasonable way. The QoE of game players in MCG systems can be generally modeled by a set of objective and subjective factors. Wang and Dey (2009) characterized user QoE by video settings, network factors, image quality, etc. *Game Mean Opinion Score (GMOS)* (Schaefer et al. 2002) has been widely used to map these factors to the value of QoE. However, these QoE models often assume that players are in the same physical context when playing games. When using mobile devices to play games, the physical context can be highly dynamic since the mobility of users will incur certain changes of their surrounding environment (e.g., where the player is, what the player is doing, and so on) (Benford et al. 2005). Mobile devices provide an opportunity to sense the physical context by analyzing information from multiple sensors such as motion sensors, light sensors, and acoustic sensors. It is important to integrate the availability of context sensing when designing a more realistic QoE model of mobile cloud gaming.

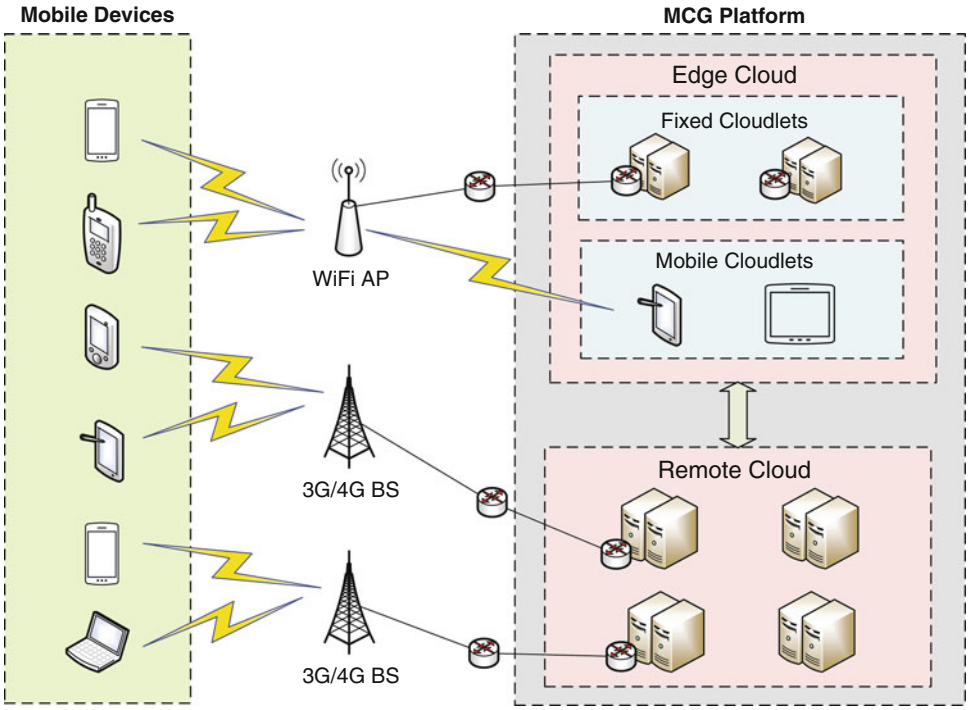
The provisioning of MCG resources also should be able to maximize the QoE of gamers (including latency, video quality, etc.). In the meanwhile, due to the cost of delivering high QoE, the MCG service provider also needs to take service cost into account during optimization. To achieve the tradeoff between the monetary cost incurred by provisioning cloud resources (e.g., CPU, GPU, bandwidth) and service quality (e.g., delay, frame rate, resolution) experienced by

mobile game players (Gao et al. 2016; Hu et al. 2016), the MCG service provider should dynamically adjust the amount of provisioned cloud resources according to the variations of user demand. Chuah et al. (2014) provided a comprehensive survey on how to efficiently leverage hardware resources to satisfy the demand of graphics rendering and video coding in cloud gaming. It is of more interests to analyze the complexities of scheduling cloud resources from a broader perspective. As the difference among game genres affects the demand pattern of cloud resources, the resource efficiency can be improved by optimizing resource allocation among different game genres jointly. However, as indicated by Chen et al. (2014), it requires further effects to solve the problem of consolidating multiple MCG tasks (e.g., rendering, video coding and transmission) on cloud servers.

Streaming gaming video in such a stringent time-constrained scenario is also a major challenge in MCG. One solution to cope with this problem is data compression. After game scenes are computed on cloud gaming servers, they have to be compressed before being streamed. This can be done in one of the three data compression schemes: (i) video compression, which encodes 2D rendered videos, (ii) graphics compress, which encodes 3D structures and 2D textures, and (iii) hybrid compression, which combines both video and graphics compress.

Architecture and Design of MCG Systems

It is challenging to architect a cost-effective MCG platform that can provide users with high QoE. As a delay-sensitive service, game players are sensitive to interaction delay during game playing. The MCG platform should be able to adjust resource allocation for mobile users dynamically in order to meet the delay constraint. According to the distance to mobile devices, the authors briefly classify existing MCG architectures into two categories, namely, *Remote Cloud* and *Edge Cloud* (as shown in Fig. 1).



Mobile Cloud Gaming, Fig. 1 Architectures of mobile cloud gaming systems

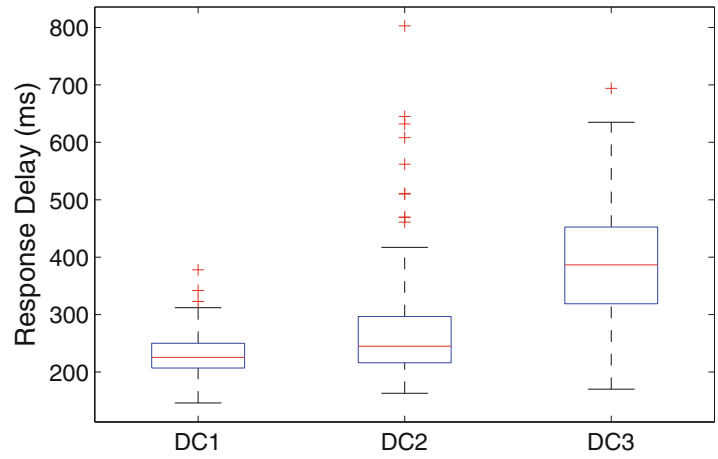
Remote Cloud refers to the architecture in which a MCG service provider relies on a remote cloud platform to deliver the mobile cloud gaming service to mobile users. The architecture of Remote Cloud has been widely adopted by leading MCG service providers, such as Ubitus and G-Cluster. Physically, the remote cloud can be provisioned on a set of geographically distributed data centers in order to serve mobile users in different regions.

As the MCG service provider can directly rent cloud resources (e.g., VM, bandwidth, storage) from the third-party cloud service providers (e.g., Amazon, Microsoft), the construction and maintenance of the remote cloud infrastructure can benefit significantly from mature services of cloud service providers. Remote cloud could be very reliable and powerful. It is also easy to expand the scale of provisioned resources according to dynamic user demands.

The major issue with the mode of the remote cloud is network latency, as most large cloud service providers only deploy their data centers at a limited number of locations. For players who are far away from any cloud data center, network latency will deteriorate their gaming experience significantly. Figure 2 shows the response delay when selecting different data centers when using the remote cloud. The requirements on high video quality and high frame rate will further exacerbate the latency problem. To achieve real-time transmission of game video streams under the mode of the remote cloud, researchers have performed quite a few research studies on video codec optimization, network transmission, and QoE adaptation jointly. As stated in Jarschel et al. (2011), the QoE of cloud gaming is highly related to downstream packet loss and downstream delay, which indicates the necessity of connecting the nearest and fastest server.

Edge Cloud is another attractive architecture proposed to address the latency problem of remote cloud, in which cloudlets (Satyanarayanan et al. 2009) close to the mobile device are responsible for task offloading in order to meet the strict latency requirement. Generally, a *cloudlet* is a kind of resource-rich computing entity with a broadband network connection in the proximity of mobile devices. There are two kinds of cloudlets: *fixed cloudlets* (e.g., desktop PC, gateway, and set-top-box) and *mobile cloudlets* (e.g., tablets, pads). As a mobile device is well connected with nearby cloudlets, the intensive computation tasks (e.g., frame rendering, video encoding) can be completely migrated to the nearby cloudlets.

In spite that edge cloud is a promising approach, several intrinsic problems should be addressed before its successful deployment in reality. First, the MCG service provided by cloudlets is not reliable and depends on the existence of cloudlets in the proximity. The problem is even worsened for the case of mobile cloudlets. Second, the decentralized nature of cloudlets makes it hard to be operated and managed. For an edge



Mobile Cloud Gaming, Fig. 2 Response delay when selecting different data centers in remote cloud

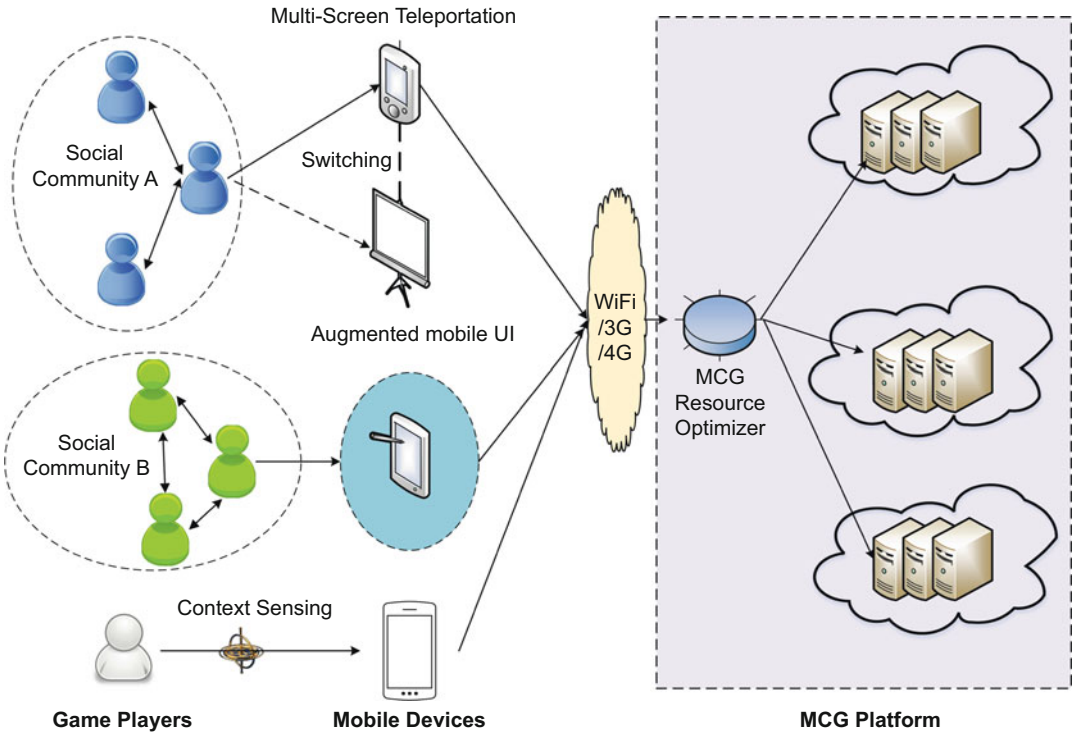
cloud with many volunteer cloudlets, the cost of cloudlet management and maintenance will be nontrivial for a MCG service provider. Third, effective incentive mechanisms should be adopted to encourage individuals to deploy more cloudlets. To provide MCG services, a cloudlet should contribute its own resources (including CPU cycles, battery energy, and disk space). Without monetary incentives, it is difficult if not impossible to stimulate resource sharing between cloudlets and mobile devices. In addition, the issues of security and privacy caused by task offloading should also be considered.

In the spectrum of architectural design of MCG platforms, *Remote Cloud* can be regarded as one end and *Edge Cloud* could be the other end. Either of them has its own pros and cons as the authors have explained in the above. The authors believe that, *Hybrid Cloud*, which is a combination of edge cloud and remote cloud, is a better architecture to support mobile cloud gaming. It can seamlessly integrate both proximate and remote cloud resources to deliver a smooth gaming experience for mobile game players.

However, the architecture of hybrid cloud will also complicate the system design. In the real scenario, task partitioning among mobile devices, cloudlets, and remote cloud servers will become very sophisticated. The decision on task partitioning needs to take the constraints on response delay, resource availability, energy consumption, and bandwidth conditions into account. In the current stage, the research on hybrid cloud is still in its infancy.

Potential Directions and Opportunities

In this section, the authors discuss a few directions and opportunities for future research on mobile cloud gaming. Figure 3 provides an illustrative example on the directions covered here, which will be explained one by one in the following parts.



Mobile Cloud Gaming, Fig. 3 An illustrative example on potential opportunities on mobile cloud gaming

Augmented User Interface for Mobile Devices

User interface plays an important role for user QoE of mobile cloud gaming. Particularly, many mobile devices (e.g., smartphones, pads) cannot support the traditional physical keyboard and mouse as the input, and only touch screen is available as the gaming control. Therefore, it is critical to augment the current user interface of mobile devices to better support mobile cloud gaming. The tracking of a mobile device can be realized by analyzing received signals such as RF signals and acoustic signals. By combining the arrival sequences of measured signal angles from two or more receivers (e.g., antennas, speakers), the movement of a mobile device can be precisely sensed (Vasisht et al. 2014; Agrawal et al. 2011). The augmented interaction techniques will significantly enhance gaming experiences on mobile devices.

Environment-Aware Mobile Game Playing

Different from fixed game consoles (e.g., desktop PCs, gaming boxes), mobile cloud gaming enables gamers to play games anywhere at anytime. Such high mobility implies that the surrounding environment of a gamer may keep changing during game playing. With a rich set of sensors (e.g., microphone, light sensor, camera, GPS, accelerometer) available on today's mobile devices, it is possible for mobile devices to sense the physical context of their surrounding environment (e.g., indoor or outdoor, fixed or moving, light or dark). Moreover, the emergence of wearable devices (e.g., smartwatches, smartglasses) shows a bright future to sense fine-grained physical context. By adaptively generating game contents according to the changing physical context, mobile game players can enjoy enriched gaming experiences. As an example, the MCG platform can adapt the quality, frame-rate, and contents of game video streams according to the light condition and moving speed of a mobile user. Such environment-aware adaptation can improve the user QoE significantly.

Integration of Social Networks with MCG

By integrating social links among gamers with the MCG system, mobile cloud gaming can provide a user-centric gaming environment, which dramatically transforms the traditional gaming experiences. Social mobile cloud gaming creates a virtual living-room experience, by allowing remote mobile gamers to play games together, watch game playing of other friends, and communicate via various communication modalities (such as text, graphics, audio, video, and so on). For example, twitch-like live video game broadcasting (Hamilton et al. 2014) has already attracted significant attention from game players. A gaming broadcaster often belongs to the same social community with his viewers. As the exchange of information flows between mobile players is supported by the MCG platform, the abundant resources in the cloud can better support the increasing number of mobile players. The MCG system can be highly scalable with the support of cloud infrastructure.

Multiscreen Teleportation of MCG Sessions

Nowadays, mobile gamers normally interact with multiple screens in their daily living environment (Hu et al. 2014). The sizes of these screens range from large (e.g., TV screen) to small (e.g., smartphone screen). To enjoy a better gaming experience, gamers are willing to teleport ongoing gaming sessions from a small screen to a large screen if without any interruption, and vice versa. Imagine that a user is playing a game on his smartphone when taking the subway back to home. Upon arriving at home, he can teleport his gaming session to the TV screen and play the game with a joystick. After leaving his apartment for dinner, he can switch the gaming session back to his smartphone. Such seamless teleportation among multiple screens will surely enhance the gaming experience of players. With the MCG platform, gaming session migration can be easily supported by the back-end cloud infrastructure.

As a promising solution to enable high-end video games to be played on resource-constrained mobile devices, the authors believe that mobile cloud gaming will definitely have a bright future in the coming era.

Definition

Mobile persuasive applications are native or mobile web applications with inbuilt persuasive features that influence the attitudes or behaviors of users.

Introduction

B. J. Fogg has introduced the concept of "persuasive technology" to frame the domain of research, design, and applications of persuasive computers Fogg 2002). Persuasive technology refers to applications and interactive media which implement psychological principles of persuasion (like credibility, trust, reciprocity, and authority) aiming at positively altering users' disposition and behavior toward a predetermined goal.

It is now widely recognized that apart from relying on humans to influence others (e.g., life coaches, nutritionists, etc.), the conscious design of persuasive computer applications as a means for influencing human behaviors can bring about positive changes in many domains, including health, personal lifestyle and well-being, safety, and environment. This underscores the importance of persuasive technology, that is, its capacity to effectively influence the attitudes or behaviors of users so as to ultimately serve the personal and/or the social good (e.g., adoption of healthy diet habits, promotion of sustainable lifestyles toward green travels, or household waste reduction). Recent advances in computing, particularly mobile computing, leverage untapped opportunities to impact users' behavior for the better. In fact, field studies have provided evidence that smartphone applications achieve higher adherence to behavior change tasks (e.g., change exercise and nutrition habits to treat obesity) compared to their web counterparts or other paper-based programs with respect to retention, engagement, and effectiveness (Carter et al. 2013).

The key objective of the article is to explore the area of mobile persuasive applications, through presenting the most typical behavioral change goals they pursue, reviewing representative popular applications, and discussing the elementary principles considered in the design of mobile persuasive systems.

Attitude and Behavioral Traits Addressed by Mobile Persuasive Applications

Mobile devices represent a useful instrument for persuasive applications as they exhibit several desired characteristics and satisfying features (e.g., the requirement to assess and motivate the physical activity of a person may be satisfied by persuasive applications which take advantage of the readings of smartphones' built-in sensors) (Kasapakis and Gavalas 2015). The diffusion of mobile devices allows to reach a much wider audience while apps are easy to disseminate through the established mobile application markets; mobile devices come with an array of inbuilt sensors and may easily couple with wearable devices (such as smart wristbands, smartwatches, etc.) to accurately estimate a variety of user activities, for instance, the type, pace, duration, and location of physical activity (e.g., number of steps taken and/or stairs climbed), which may then be translated to meaningful statistical indicators (e.g., calorie consumption).

Recently, persuasion principles have been applied to the design of mobile applications which aimed at such diverse behavioral change goals (Gardeli et al. 2017; Langrial et al. 2013, 2017):

- Stimulation of enhanced physical activity: "fitness" apps supporting walking, running, hiking, and cycling workout
- Improvement of well-being and adoption of healthy lifestyles: monitoring of physical exercise, nutrition intake, smoke cessation, alcohol intake reduction, weight management, etc.

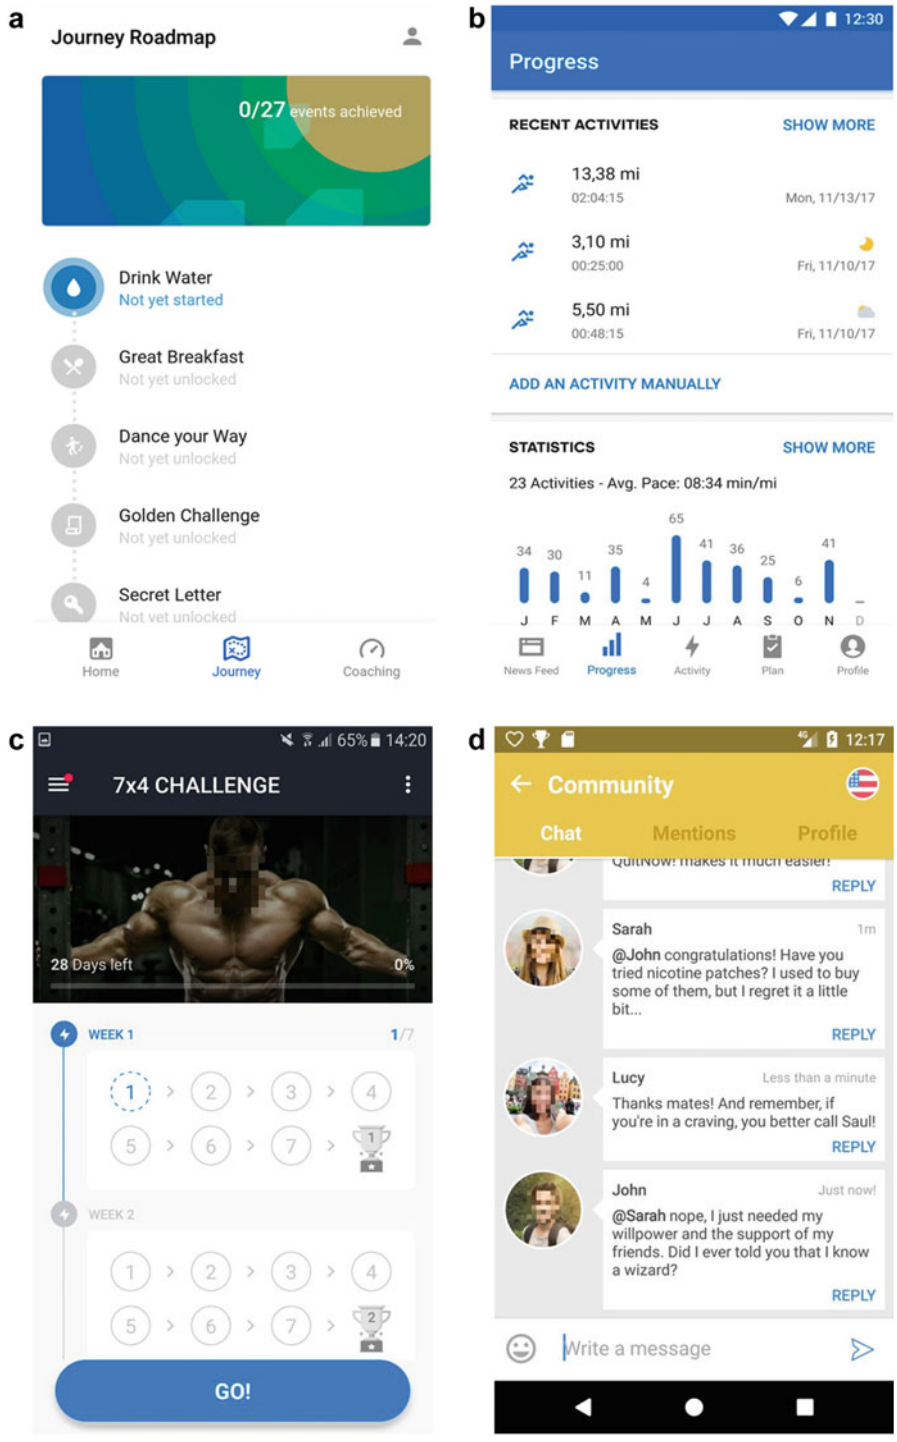
- Addressing health problems (e.g., obesity, heart disease, type 2 diabetes) and adherence to prescribed medication intake
- Mood monitoring, stress, and anger management
- Adoption of low-carbon lifestyle, e.g., encouragement to embrace environmentally friendly transport practices
- Preservation of shared physical resources and environmental awareness
- Improvement of driving behavior and safety

The number of mobile persuasive applications, serving the abovementioned behavioral change goals, has proliferated in the recent years. These applications employ several behavior change techniques (Conroy et al. 2014) to enhance awareness, increase motivation, and engage users with the task/activity at hand (a theoretical discussion of the key design considerations for such applications is provided in the next Section). For instance: the *Fabulous – Self-Care* app (https://play.google.com/store/apps/details?id=co.thefabulous.app) supports users in goal setting through monitoring tasks completion toward adopting healthy habits (see Fig. 1a); the *Runtastic Running* guides (https://play.google.com/store/apps/details?id=com.runtastic.and roid) users throughout running/jogging sessions via a voice coach while also providing detailed feedback on their performance (see Fig. 1b); the *Home Workout* app (https://play.google.com/store/apps/details?id=homeworkout.homeworkouts.noequipment) rewards users with badges when successfully completing a weekly program of exercises (see Fig. 1c); the *QuitNow! Quit Smoking* app (https://play.google.com/store/apps/details?id=com.EAGINsoftware.dejaloYa) allows social interaction and progress comparison among its users to further motivate them in quitting smoking (see Fig. 1d). It is noted that the illustrated apps are not chosen as the best manifestations of the persuasive technology but, instead, as representative examples of mobile persuasive applications on the basis of their popularity (>1M downloads).

Persuasion Design for Mobile Applications

Principles of social psychology, context-aware decision-making, as well as engagement strategies are commonly utilized as means of persuasive design throughout the design process of products and tools intended to influence positive behavioral changes. Oinas-Kukkonen and Harjumaa (2009) summarized their empirical findings to several postulates that should be taken into account when designing or evaluating persuasive systems. Firstly, persuasive systems should decompose persuasion to a multilevel process, as users are more likely to be persuaded when performing a series of incremental tasks. Designers should also take into account that technology is not neutral as it critically affects user behavior; hence, this should be communicated to users in order not to lower the level of persuasion. Furthermore, users are more likely to be persuaded when making commitments, and therefore persuasive systems should facilitate users in completing those commitments by organizing user tasks accordingly and offering consistency. Moreover, it is important that persuasive systems should support both a direct route to persuasion that focuses on the quality and punctuality of the information and also an indirect route that uses peripheral cues to associate positivity with the message without requiring much effort or information processing. Finally, persuasive systems should be useful to users and rather usable while also being discreet so as not to interrupt users when performing primary tasks.

So far, the Persuasive Systems Design (PSD) model has been the most generic conceptual framework in assistance of persuasive systems designers (Oinas-Kukkonen and Harjumaa 2009). The PSD model underlines the significance of persuasion context by addressing the intent (intended change), the event (use, users, and the context), and the strategy (persuasive message and delivery route). Moreover, it identifies four basic design principles to be incorporated in persuasive applications, some of which have been adopted from Fogg (2002):



Mobile Persuasive Applications, Fig. 1 (**a**) *Fabulous – Self-Care* app, health goal setting (image courtesy of TheFabulous); (**b**) *Runtastic Running*, self-monitoring of running performance (image courtesy of runtastic GmbH); (**c**) *Home Workout* app badge rewards (image courtesy of Leap Fitness Group); (**d**) *QuitNow! Quit Smoking*, social interaction with other users performing alike tasks. (Image courtesy of Fewlaps)

Mobile Persuasive Applications, Table 1 Methods employed by popular persuasive applications for addressing the persuasive design principles of the PSD model

Title	Fabulous – Self-Care	Runtastic Running	Home Workout	QuitNow! Quit smoking
Scope	Supporting users in adopting healthy habits	Motivating users to exercise (running/jogging)	Persuading users to exercise (gymnastics)	Supporting users to quit smoking
Primary task support	Collection of user data (e.g., sleep and training habits); illustration of detailed progress charts based on user goals	Collection of user data (e.g., age, weight, height); provision of custom training plans according to user goals (e.g., weight loss plan); illustration of detailed progress charts	Collection of user data (e.g., age, weight, height); provision of training plans according to user goals (e.g., full body exercise plan); illustration of detailed progress charts	Collection of user data (e.g., number of cigarettes smoked per day); illustration of detailed progress charts
Dialogue support	Task reminders via notifications/alarms; voice coach messages	Voice coach guidance throughout training sessions; leaderboard support; task reminders via notifications/alarms	Voice coach guidance throughout training sessions; badge/achievements rewards; task reminders via notifications/alarms	Badge/achievements rewards; task reminders via notifications/alarms; provision of an automated chat bot which supports users with scientific facts relevant to quitting smoking
Credibility support	Provision of verified scientific data via personalized messages about the importance of each healthy habit	Usage of GPS for accurate running/jogging distance measurement; integration with wearable fitness trackers to further increase the accuracy of measurements	The application can be linked and transfer data to *Google Fit* (https://www.google.com/fit/), the official fitness tracker app of Google	Provision of an automated chat bot which supports users with scientific facts relevant to quitting smoking; provision of a FAQ section with verified methods for quitting smoking
Social support	Users can share and compare their progress with friends through a dedicated service and popular social media platforms	Users can share and compare their progress with friends through a dedicated service and popular social media platforms	–	Users can share and compare their progress with friends through a dedicated service and popular social media platforms

- *Primary task support*, which involves support of the user to carry out her primary task through reduction (decomposition of complex behaviors into simple tasks), guidance along the attitude change process, and provision of information tailored to users' potential needs or interests, allowing users to self-monitor their own performance.
- *Dialogue support*, namely, enabling users to receive feedback while moving toward their target behavior through offering praise (via words, images, symbols, or sounds based on user behaviors), providing virtual rewards (as a credit for performing the target behavior), and reminding users of their tasks.
- *Credibility support*, which relates with designing systems so that they are more credible through inculcating trustworthiness (providing information that is truthful, fair, and unbiased), offering content incorporating expertise (i.e., knowledge, experience, and competence), highlighting the real people or

organizations behind the system's content or services, and providing means to verify the accuracy of content.

- *Social support* which relates with fostering user motivation through social learning (observing other users who perform similar target behaviors), social comparison (comparing performance with the performance of other users), and normative influence (means for gathering together people who aim at the same goal).

Table 1 provides an overview on the methods employed by the example applications illustrated in Fig. 1 to address the basic design principles of the PSD model

Further to the persuasive design principles of the PSD, *gamification* (i.e., the use of game design elements in non-gaming contexts) is increasingly used as a design strategy in the development of persuasive systems (Cugelman 2013; Gardeli et al. 2017). The design of gamified applications entails the incorporation of appropriate motivational and playful elements in the core of interactive systems in order to attract and retain users' interest while achieving their goals (Papagiannakis 2018). Thus, the gamification approach is particularly relevant to the design of mobile persuasive applications. One of the most successful examples of gamification for persuasive systems is Zombies, Run! (https://play.google.com/store/apps/details?id=com.sixtostart.zombiesrunclient). In effect, users are immersed in running game sessions, being provided voice guidance to achieve exercise goals while also trying to survive the "zombie apocalypse." Also, users can share and compare their progress with other users via the complementary community website ZombieLink (https://zombiesrungame.com/zombielink/home/, see Fig. 2).

Conclusions and Research Prospects

Sufficient evidence already exists that smartphone applications may effectively support people in pursuing behavior change goals. Nevertheless, despite the recent conceptualization of generic methodologies and guidelines for designing persuasive systems (Oinas-Kukkonen and Harjumaa 2009), the selection and combination of design elements and technologies that effectively support behavioral change represent an open research issue. There is a growing need for field studies (involving real users for relative prolonged time periods) in a variety of usage situations and persuasion contexts that will allow

deeper understanding of the persuasion context and will eventually provide rich feedback on various design choices with respect to the target group and the desired outcomes (Langrial et al. 2017).

Although the PSD model represents a solid framework that suggests must-have design elements of persuasive applications, the formulation of design strategies that specifically suit the unique characteristics of mobile applications is still in need. For instance, the effect of contextual factors easily captured by mobile devices (e.g., location, activity, environmental and social context, etc.) could be considered in a revised PSD model. Potential revisions of PSD should also include the incorporation of selected gamification principles.

Modeling and Mesh Processing for Games

Jin Huang
Zhejiang University, Hangzhou, China

Synonyms

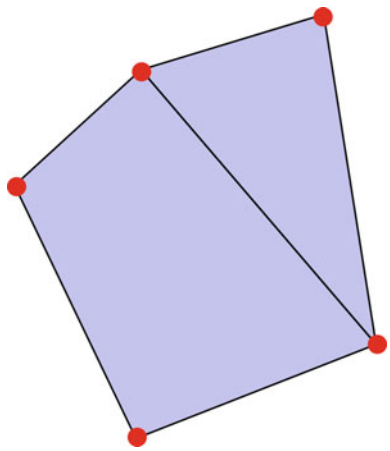
Digital geometry processing; Polygonal modeling

Definition

Mesh modeling is the process of constructing a polygonal mesh from scratch by basic operations or editing an existing mesh for a desired geometric shape. Mesh processing includes various operations which modify input mesh for specific purpose, which usually preserve overall shape or local details.

There are various methods to represent a 3D surface, such as NUBRS and implicit surface. Among these methods, polygonal mesh is a very popular one for game industry, for it is simple, flexible, and efficient. We introduce the modeling and processing of polygonal mesh, or, for short, mesh.

A mesh is composed of some basic elements: vertices (red dots), edges (black lines), and faces (light blue areas). Each vertex stands for a specific position in a 3D space, each edge connects two vertices, and each face is a surface patch bounded by a loop of edges. Theoretically, a face is bounded by any number of edges, but triangular and quadrilateral faces are the most common ones.

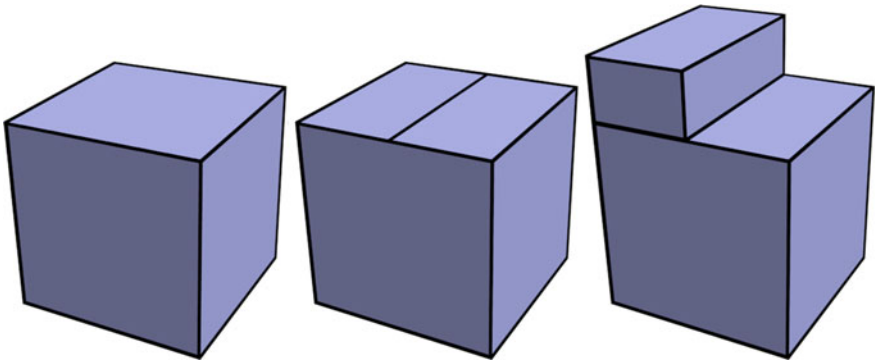


To model a surface by mesh, one can first create the vertices and then build the edges and faces. Such a very preliminary way is very inefficient. A widely applied method is to modify a simple mesh into a desired one by repeatedly applying several basic operations. Two of the most important operations are split and extrude. The split operation (center of the inset) cuts a face into smaller ones, and the extrude operation (right of the inset) builds a prism using an existing face as the base (Fig. 1). Other advanced modeling methods usually adopt other surface representations, such as NURBS and implicit surface, and then convert the modeling result into a mesh.

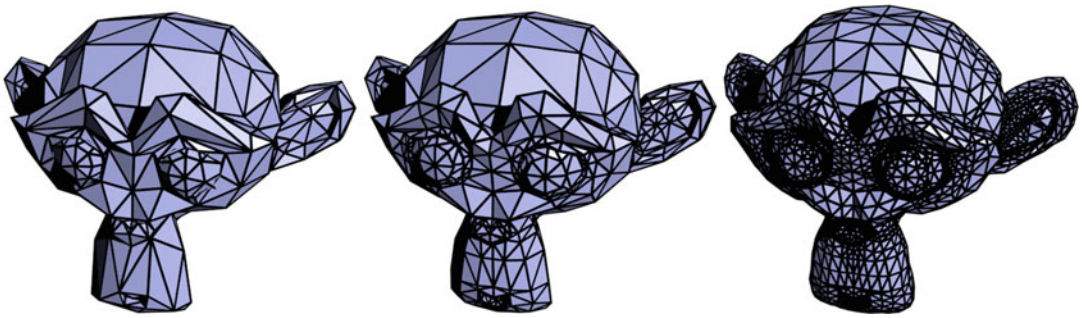
Mesh processing refers to applying certain operations on a mesh to turn it into a desired one. Thus, some modeling methods can also be viewed as mesh processing. For games, simplification (left of the inset) (Fig. 2) and subdivision (right of the inset) could be the most important processing over an input mesh (center of the inset), which adjust the mesh to balance the accuracy and performance.

Simplification turns a mesh into an approximated one with less number of faces, which sacrifices the quality to reduce the storage and rendering cost. The common strategy to simplify a mesh is to recursively remove basic elements (e.g., vertices, edges, or faces) in order. The order is critical and usually determined according to the error introduced by removing the elements. The error can be measured in many different ways. A typical measurement is named as "Quadric Error Metric," (Garland et al. 1997) which measures the change of geometric shape by an easy-to-compute quadric form in terms of the vertex positions. Other measurements could take the change of normal distribution, texture, and other factors into account. During the simplification, one could also apply application-dependent restrictions to the procedure, such as maximal edge length, minimal angle, and sharp feature preserving, etc.

On the contrary, subdivision increases the number of faces for better accuracy. It uses a set of topological rules to change and add more elements into a mesh and then put the updated vertices into certain positions according to geometric rules. Recursively refining a mesh can result in a sequence of mesh with finer and finer resolution. The limit one is smooth almost everywhere and tightly related to B-spline and other algebraic surface. The most simple and widely used subdivision schemes include Catmull-Clark (Stam



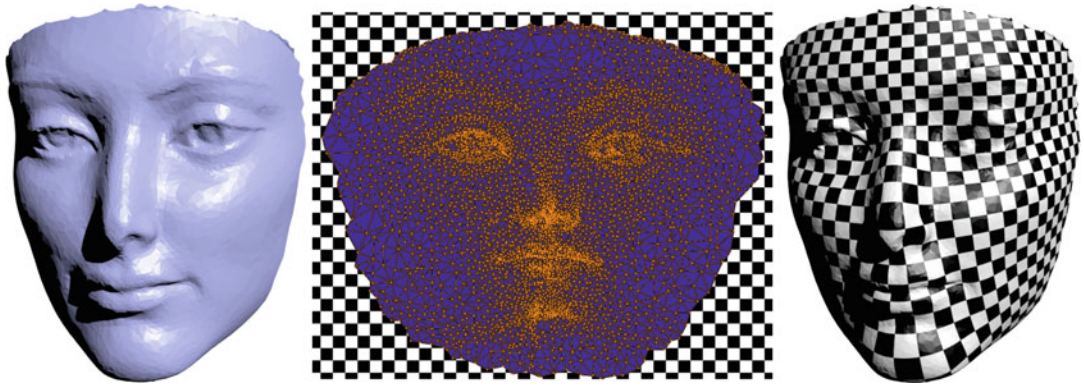
Modeling and Mesh Processing for Games, Fig. 1 starting from a cube (left), use split (middle) and extrude (right) operations to model a shape



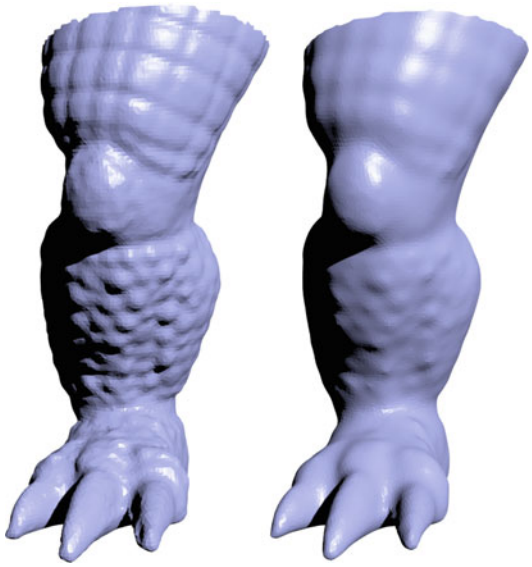
Modeling and Mesh Processing for Games, Fig. 2 Simplify (left) and subdivide (right) an input mesh (middle)

1998), Doo and Sabin (1978), and Loop (1987). The above subdivision schemes refine the mesh in a whole and may introduce too many elements unnecessarily. The adaptive subdivision strategy only refines part of the model that needs more elements. Modern graphics processing unit (GPU) is able to perform subdivision very efficiently. Therefore, to render a high quality surface, one can just send a simplified mesh with a small number of faces into GPU, and let GPU tessellate it into a high-quality mesh with a large number of faces. Integrating simplification and subdivision does not only help rendering, but can also be helpful in network environment.

Mesh processing also includes a lot of other operations, which does not change the topology but only changes the vertex positions, such as smoothing and enhancement. These two operations change the detail of the mesh but roughly keep its shape. Such operations view the shape represented by mesh as a signal and modify the high frequency part. Such types of mesh processing are usually related to Laplacian-based methods and tightly related to spectral analysis (Taubin 1995). For example, the smoothing operation reduces high frequency details from the input mesh (left of the inset), which is similar to a low-pass filter and results in a mesh with smoother shape (right of the inset). On the contrary, some of the mesh processing, such as deformation and animation, keep the detail but change the overall shape. Many state-of-the-art deformation and animation methods also found the base on Laplacian of the mesh and adopt many differential geometry concepts to characterize the "detail" to be preserved (Huang et al. 2006) (Fig. 3).



Modeling and Mesh Processing for Games, Fig. 3 parameterization turns a 3D surface mesh (left) to a 2D planar one (middle), which helps to map a texture image back to the mesh (right)



General mesh processing even includes some operations that neither change the topology nor geometry. Take parameterization as an example (Hormann et al. 2007), it computes a mapping (middle of the inset) from a planar domain to a mesh (left of the inset) so that a planar signal can be transported onto the mesh (right of the inset). Texturing is a typical application of parameterization, which enhances the appearance of a mesh by mapping an image onto the mesh.

Monte-Carlo Tree Search

Mark H. M. Winands
Department of Data Science and Knowledge Engineering, Maastricht University, Maastricht, The Netherlands

Synonyms

MCTS; UCT

Definition

Monte-Carlo Tree Search (MCTS) (Coulom 2007; Kocsis et al. 2006) is a best-first search method that does not require a positional evaluation function. It is based on a randomized exploration of the search space. Using the results of previous explorations, the algorithm gradually builds up a game tree in memory and successively becomes better at accurately estimating the values of the most promising moves. MCTS consists of four strategic steps, repeated as long as there is time left (Chaslot et al. 2008b). The steps, outlined in Fig. 1, are as follows:

1. In the *selection step*, the tree is traversed from the root node downward until a state is chosen, which has not been stored in the tree.
2. Next, in the *play-out step*, moves are chosen in self-play until the end of the game is reached.
3. Subsequently, in the *expansion step*, one or more states encountered along its play-out are added to the tree.
4. Finally, in the *backpropagation step*, the game result r is propagated back along the previously traversed path up to the root node, where node statistics are updated accordingly.

Structure of MCTS

MCTS usually starts with a tree containing only the root node. The tree is gradually grown by executing the selection, play-out, expansion, and backpropagation steps. Such an iteration is called a full simulation. After a certain number of simulations, a move is chosen to be played in the actual game. This final move selection is based on the highest score or alternatively the number of times being sampled. The detailed structure of MCTS is discussed by explaining the four steps below.

Selection

Selection chooses a child to be searched based on previous information. It controls the balance between exploitation and exploration. On the one hand, the task consists of selecting the move that leads to the best results so far (exploitation). On the other hand, the less promising moves still have to be tried, due to the uncertainty of the simulations (exploration).

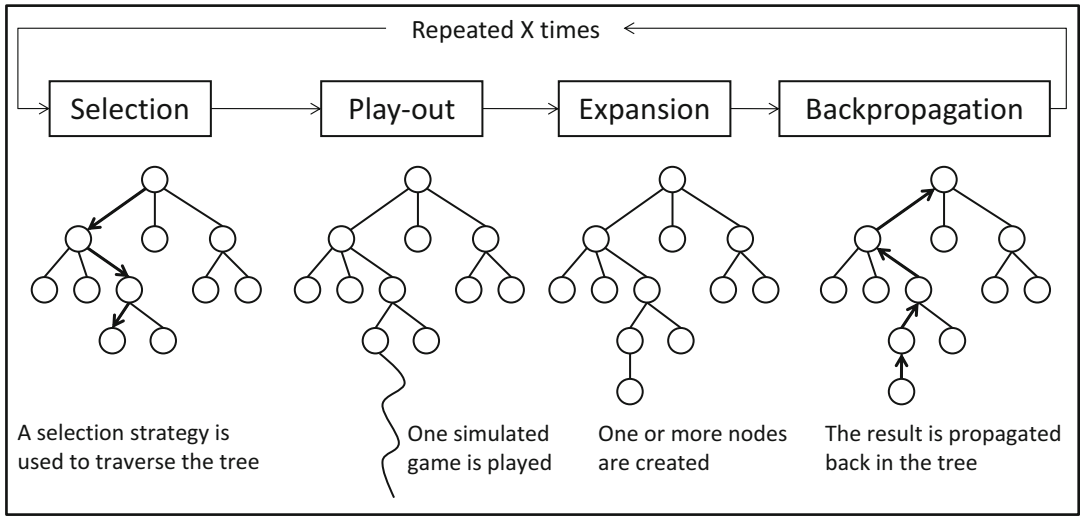
Several *selection strategies* (Browne et al. 2012) have been suggested for MCTS such as BAST, EXP3, and UCB1-Tuned, but the most popular one is based on the UCB1 algorithm (Auer et al. 2002), called UCT (**U**pper **C**onfidence Bounds applied to **T**rees) (Kocsis et al. 2006). UCT works as follows. Let I be the set of nodes immediately reachable from the current node p. The selection strategy selects the child b of node p that satisfies Formula 1:

$$b \in \arg\max_{i \in I} \left(v_i + C \times \sqrt{\frac{\ln n_p}{n_i}} \right) \quad (1)$$

where v_i is the value of the node i, n_i is the visit count of i, and n_p is the visit count of p. C is a parameter constant, which can be tuned experimentally (e.g., $C = 0.4$). The value of v_i should lie in the range [0, 1]. In case a child has not been stored in the tree or has not been visited yet, a default value is assumed. For example, the maximum value that a node could obtain by sampling (i.e., $v_{\max} = 1$) is taken.

Play-Out

When in the selection step a state is chosen, which has not been stored in the tree, the play-out starts. Moves are selected in self-play until the end of the



Monte-Carlo Tree Search, Fig. 1 Outline of Monte-Carlo Tree Search (adapted from Chaslot et al. 2008b; Winands et al. 2010)

game is reached. This task might consist of playing plain random moves or – better – semi-random moves chosen according to a *simulation strategy*. Smart simulation strategies have the potential to improve the level of play significantly. The main idea is to play interesting moves based on heuristics. In the literature this play-out step is sometimes called the roll-out or simulation.

Expansion

Expansion is the procedure that decides whether nodes are added to the tree. Standard the following *expansion strategy* is sufficient in most cases: one node is added per simulation (Coulom 2007). The added leaf node L corresponds to the first state encountered during the traversal that was not already stored. This allows to save memory and reduces only slightly the level of play.

Backpropagation

Backpropagation is the procedure that propagates the result r of a simulated game t back from the leaf node L, through the previously traversed nodes, all the way up to the root. If a game is won, the result of a player j is scored as $r_{t,j} = 1$, in the case of a loss as $r_{t,j} = 0$, and a draw as $r_{t,j} = 0.5$. To deal with multiplayer games, the result is backpropagated as a tuple of size N, where N is the number of players. For instance, if Player 1 and Player 3 both reach a winning condition in a 3-player game, then the result r is returned as the tuple $\left(\frac{1}{2}, 0, \frac{1}{2}\right)$. Propagating the values back in the tree is performed similar to $\max^n$ (Sturtevant 2008).

To compute the *value* v_i of a node i, a *backpropagation strategy* is applied. Usually, it is calculated by taking the average of the results of all simulated games made through this node (Coulom 2007), i.e., $v_i \leftarrow R_{i,j}/n_i$, where j is the player to move in its parent node p and $R_{i,j} \leftarrow \sum_t r_{t,j}$ the cumulative score of all the simulations.

MCTS Enhancements

Over the past years, several enhancements have been developed to improve the performance of MCTS (Browne et al. 2012). First, there are many ways to improve the selection step of MCTS. The major challenge is how to choose a promising node when the number of simulations is still low. Domain-independent techniques that only use information gathered during the simulations are Transposition Tables, Rapid Action Value

Estimation (RAVE), and Progressive History (Childs et al. 2008; Gelly et al. 2012; Nijssen and Winands 2011). Techniques that rely on hand-coded domain knowledge are, for instance, Move Groups, Prior Knowledge, Progressive Bias, and Progressive Widening/Unpruning (Chaslot et al. 2008b; Childs et al. 2008; Gelly et al. 2012). The used heuristic knowledge may consist of move patterns and even static board evaluators. When a couple of these enhancements are successfully incorporated, the C parameter of UCT becomes usually very small or even zero.

Next, the play-outs require a simulation strategy in order to be accurate. Moves are chosen based on only computationally light knowledge (Gelly et al. 2012) (e.g., patterns, capture potential, and proximity to the last move). Adding computationally intensive heavy heuristic knowledge in the play-outs (such as a 1- or 2-ply search using a full board evaluator) has been beneficial in a few games such as Chinese Checkers and Lines of Action. When domain knowledge is not readily available, there exist various domain-independent techniques to enhance the quality of the play-outs, including the Move-Average Sampling Technique (MAST), Last-Good-Reply Policy, and N-Grams (Tak et al. 2012). The principle of these techniques is that moves good in one situation are likely to be good in other situations as well.

The basic version of MCTS *converges* to the game-theoretic value, but is unable to prove it. The MCTS-Solver technique (Winands et al. 2010) is able to prove the game-theoretic value of a state with a binary outcome (i.e., win or loss). It labels terminal states in the search tree as a win or loss and backpropagates the game-theoretic result in a $\max^n$ way (Nijssen and Winands 2011). For games with multiple outcomes (e.g., win, loss, or draw), the technique has been extended to Score Bounded Monte-Carlo Tree Search (Cazenave and Saffidine 2011).

Finally, to utilize the full potential of a multi-core machine, parallelization has to be applied in an MCTS program. There exist three different parallelization techniques for MCTS: (1) *root parallelization*, (2) *leaf parallelization*, and (3) *tree parallelization* (Chaslot et al. 2008a). In root parallelization, each thread has its own MCTS tree. When the allotted search time is up, the results of the different trees are combined. In leaf parallelization, one tree is traversed using a single thread. Subsequently, starting from the leaf node, play-outs are executed in parallel for each available thread. Once all threads have finished, the results are backpropagated. When using tree parallelization, one tree is shared, in which all threads operate independently. For shared memory systems, tree parallelization is the natural approach that takes full advantage of the available bandwidth to communicate simulation results (Enzenberger and Müller 2010).

Historical Background

Classic search algorithms such as A*, $\alpha\beta$ search, or Expectimax require an evaluator that assigns heuristic values to the leaf nodes in the tree. The 15-puzzle and the board games backgammon, chess, and checkers are instances where this approach has led to world-class performance. However, for some domains constructing a strong static heuristic evaluation function has been a rather difficult or an even infeasible task.

Replacing such an evaluation function with Monte-Carlo sampling was proposed in the early 1990s. Abramson (1990) experimented with these so-called Monte-Carlo evaluations in the games of tic-tac-toe, Othello, and chess. In 1993 Bernd Brügmann was the first to use Monte-Carlo evaluations in his 9×9 Go program Gobble. The following years, the technique was incorporated in stochastic games such as backgammon (Tesauro et al. 1997) and imperfect-information games such as bridge (Ginsberg 1999), poker (Billings et al. 1999), and Scrabble (Sheppard 2002).

In the early 2000s, the Monte-Carlo approach received new interest in the Computer Go domain (Bouzy and Helmstetter 2004). Bruno Bouzy's Monte-Carlo Go engine Indigo had some limited success as the main challenge was to effectively combine Monte-Carlo evaluations with game-tree search. The breakthrough came when Coulom presented the MCTS approach at the 2006 Computers and Games Conference (Coulom 2007). He

subsequently demonstrated its strength by winning the 9 × 9 Go tournament at the 12th ICGA Computer Olympiad with his MCTS engine Crazy Stone. Simultaneously Kocsis and Szepesvári (Kocsis et al. 2006) introduced the MCTS variant UCT. Its selection strategy became the standard for many MCTS engines (Browne et al. 2012). Techniques such as RAVE, Prior Knowledge, Progressive Bias, and Progressive Widening (Chaslot et al. 2008b; Gelly et al. 2012) were needed to make MCTS effective in many challenging domains such as 19 × 19 Go. Parallelization (Enzenberger et al. 2010; Gelly et al. 2012) has enabled MCTS to compete with human Go Grandmasters. As of 2014, an MCTS engine can beat a 9-dan professional player with only a four-stone handicap, whereas a decade ago 20 stones could be given.

Applications

In the past few years, MCTS has substantially advanced the state of the art in several abstract games (Browne et al. 2012), in particular Go (Gelly et al. 2012), but other two-player deterministic perfect-information games include Amazons (Lorentz 2008), Hex (Arneson et al. 2010), and Lines of Action (Winands et al. 2010). MCTS has even increased the level in multiplayer games such as Chinese checkers (Sturtevant 2008) and games with stochasticity and/or imperfect information such as Kriegspiel (Ciancarini and Favini 2010), Lord of the Rings: The Confrontation (Cowling et al. 2012), and Scotland Yard (Nijssen and Winands 2012). In the General Game Playing competition, where an agent has to play many different abstract games without any human intervention, MCTS has become the dominant approach as well (Björnsson and Finnsson 2009).

Besides application to abstract games, MCTS has made inroads in the video game domain. It has been applied in the arcade game Ms. Pac-Man for controlling either the Ghosts or the Pac-Man (Nguyen and Thawonmas 2013; Pepels et al. 2014). The technique has been used for resource allocation and coordination in the turn-based strategy game Total War: Rome II and for tactical assault planning in the real-time strategy game Wargus (Balla et al. 2009). The MCTS framework has also shown promise in the General Video Game AI Competition (Perez et al. 2014), where the goal is to build an agent that is capable of playing a wide range of (simple) video games.

MCTS has also been applied in puzzle games such as SameGame (Schadd et al. 2012) where it is hard to design an admissible evaluation function for A* or IDA*. As these games are close to scheduling and optimization problems, MCTS has been introduced in real-life applications. They are, for instance, high energy physics (Ruijl et al. 2014), patient admission scheduling (Zhu et al. 2014), and interplanetary trajectory planning (Hennes et al. 2015).

Future Directions

MCTS does not require a positional evaluation function, overcoming partially the knowledge acquisition bottleneck. It is therefore a promising method when an agent has to play a wide range of games as is fostered in the General (Video) Game Playing competitions. However, for MCTS to work effectively, search-control knowledge is required to guide the simulations. Domain-independent techniques are able to boost the decision quality of an MCTS engine, but for achieving expert level hand-coded domain knowledge is incorporated to grasp high-level context. Instead of being hand-coded by the programmer, a future research direction is to automatically discover, extract, represent, and tune this control knowledge during online search.

MCTS has been quite successful in abstract games; however, the number of successful applications in modern video games with high fidelity is rather limited. There are three challenges for applying MCTS in these games. (1) In these video games, the action space is large if not infinite, and the state space is often continuous. For MCTS to work effectively, the game world has to be abstracted automatically in such a way that (i) the number of possible moves is limited and (ii) the number of moves required to finish the

game is reduced as well. (2) These games have a high degree of uncertainty, not only due to non-determinism (the outcome of a move cannot be predicted) or imperfect information (certain information is hidden for a player) but also because of incomplete information (the behavior of the physics engine may be unknown). For non-determinism and imperfect information, MCTS enhancements have been investigated to a limited number of abstract games (Cowling et al. 2012), but even less for video games. Dealing with incomplete information in the MCTS framework is a largely unexplored terrain. (3) Due to the real-time property the amount of deliberation time is limited. MCTS has to generate a sufficient number of simulations in a short time as otherwise the decision quality is quite low (Björnsson and Finnsson 2009).

Definition

Motion matching is a data-driven technique for animating virtual characters in real-time with a high degree of realism. This method relies on a large set of preprocessed motion data, typically captured using motion capture devices. In a game loop, the motion matching system continually searches a motion database to find the most suitable short motion clip to fulfill the user's intentions and the game requirements. The chosen motion is then seamlessly blended with the currently playing character animation to create realistic transitions.

Introduction

Video games and other interactive applications are constantly striving for higher levels of graphical fidelity and immersion. While visuals are certainly important, the realism of the dynamic

interactions between characters and their virtual worlds may be even more crucial to achieving a sense of immersion. Therefore, animation systems play a vital role in modern game development. As graphics continue to evolve and become more detailed, there is a corresponding need for equally detailed world dynamics and animations. An effective animation system must be able to handle an increasing number of interactions and support the creation of rich virtual worlds.

Conventional animation systems, which rely heavily on hand-crafted state machines and parametric blending of animations, are not suitable for many scenarios because they do not scale well. Manually modeling every potential interaction with a state machine is impractical as the number of possible state transitions increases combinatorially. To address this issue, motion matching (Büttner and Clavet 2015) was developed as a data-driven animation technique that does not explicitly model every possible interaction. Instead, it searches an animation database for the most suitable short sequence for a given set of circumstances.

Motion matching has been widely adopted by game studios, including For Honor (Clavet 2016), EA Sports UFC 3 (Harrower 2018), The Last of Us 2 (Michal and Zhuravlov 2021), and Control (Ilkka and Ville 2021).

Character Animation

In order to create an animation system, a mathematical model of the character and its movements over time must be developed. This includes defining the foundational concepts and data structures used to represent character animations. Typically, animations are made up of discrete character poses that are stored and interpolated through as time progresses.

The central element in character animation is the affine transformation, which concisely describes a position and direction in an affine space. An affine transformation A is defined by a translation $p \in \mathbb{R}^3$ and a rotation $q \in \mathbb{S}^3$, both relative to an affine space. Affine transformations can also include a scale component, but in the case of human bones, which are rigid and of constant length, this component is typically assumed to be equal to one. For cartoony characters, the scale component could vary.

Equation 1 is used to compose an affine transformations A_0 over A_1. This equation first translates A_1 by rotating it with the q component of A_0 and adding the p component of A_0. It then computes the new orientation of A_1 by composing q_0 with q_1, effectively applying the two rotations in order.

$$\begin{aligned} p &= q_0 \times p_1 + p_0. \\ q &= q_0 \times q_1. \end{aligned} \tag{1}$$

Skeletal Mesh Animation

Virtual characters are typically represented using skeletal meshes, which consist of a set of polygons that make up the character's surface and a hierarchy of interconnected bones used to deform the polygons. The polygons are composed of vertices, and the way in which each bone influences the movement of the polygons it is associated with is determined by skin weights, which are assigned to each vertex of the mesh. This process, known as mesh skinning, is used to bind the character's surface to its bones. However, the specifics of mesh skinning are not covered here.

It is useful to model a chain of bones such that rotating a bone automatically applies the same rotation to its children. To do this, each bone i is modeled using an affine transformation $A_i^{I(i)}$ that is defined relative to the affine space of its parent $A_{I(i)}^{I(I(i))}$, where $I(i)$ is a function that maps bone i to its parent. This is achieved by applying the inverse transformation of the parent, $A^{I(i)}i = A^{-1}I(i) \times A_i$. The pose of a character at frame k is then represented as an ordered set of N affine transformations, $P_k = \left[A_{0,k}^W, A_{1,k}^{I(1)}, \ldots, A_{N,k}^{I(N)}\right]$. The root bone's affine transformation, A_0^W, is special and is defined relative to the coordinate system of the game world, as indicated by the W superscript.

The above construction has the property that translating the whole set of bones in the game world only involves translating A_0^W. However, when rendering the character, converting every relative transformations to the game world coordinate system is necessary. Each bone has exactly one parent, meaning that one can compute every world space affine transformations in a single

Motion Matching: Data-Driven Character Animation Systems, Fig. 1 The skeletal mesh of a freely available 3D model. (© Unity Technologies Japan/UCL) The multiple polygons composing the characters are delineated with black lines, and the bone hierarchy is displayed with red spheres and stripes

ordered pass starting from the root bone using forward kinematics. For example, if the bones with indices 1 and 2 have parents indexed as 0 and 1, respectively, the calculations will be $A_1 = A_0^W \times A_1^0$ followed by $A_2 = A_1 \times A_2^1$. (Fig. 1).

A skeletal mesh animation is therefore a sequence of character poses:

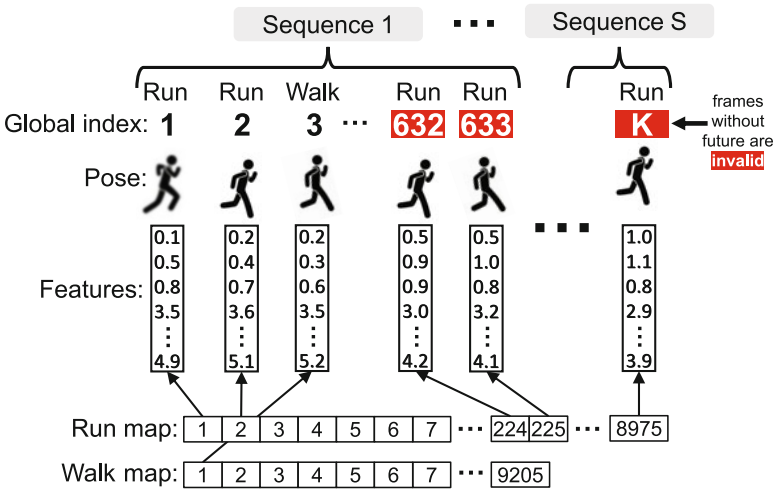
$$s = [P_0, P_1, \ldots, P_n] \tag{2}$$

where n is the number of frames in the animation. For simplicity, it is assumed that the animations are densely sampled at each frame and that the sample rate is equal to the application frame rate. Playing back an animation in this context is equivalent to flipping through the pages of a flipbook.

Motion Matching

Motion matching is a technique that works by defining the high-level goals of the animation system and searching a database for the short subset of an animation that best matches those goals. The system defines goals with concrete values such as the desired character position in 60 frames or the foot starting position at the start of the sought short sequence. This obtained pose sequence is then intelligently blended into the already playing animation. When the goals of the animation system are updated or a fixed interval of time has passed, a new search is performed to find an appropriate short pose sequence and blend it in. This continuous blending, coupled with the goal of minimizing the new sequence's disparity through the search process, is key to synthesizing smooth character motion.

To enable the search, the poses P_k of each animation sequence s are concatenated to form K consecutive frames. An algorithm is then used to search for a frame $k^* \in \mathbb{N} : k^* < K$ from which to start playing back a pose sequence. Figure 2 illustrates the database structure that contains a global index mapping to each existing pose. During the search, the selected frame k^* best conforms to the animation system's goals. To find the most similar frame, a set of numerical features that characterize the situation at each frame k is extracted and compared to query features, which encode the desired properties of the wanted sequence. Choosing the appropriate information to put in the



Motion Matching: Data-Driven Character Animation Systems, Fig. 2 Schematic of a motion database. All pose sequences are concatenated, forming K frames indexing an array of poses. Each frame is associated with a numerical feature vector that describes the situation at the frame. Also, a mapping per action in the dataset is maintained to search only a relevant subset of the data. Frames at the end of sequences are invalid as they have no defined future and therefore are not valid candidates to start playing back the animation

features, which consists of designing a query space, is fundamental to a working implementation of motion matching.

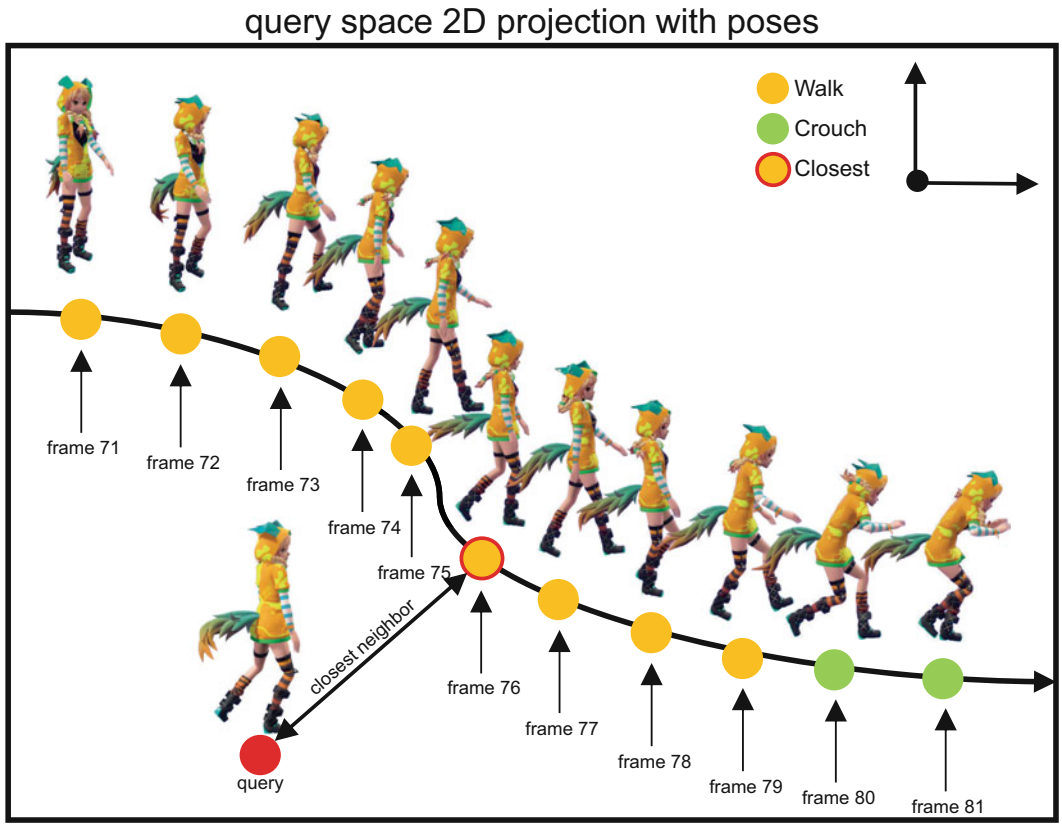
Section "Query Space" introduces concrete feature definition and usage, section "Search" presents the search algorithm, section "Blending" describes the motion blending procedure, section "Procedural Adjustments" introduce post-processing steps, and section "Making Queries" touches upon how to create the query features.

Query Space

The features reflect the high-level goals of the search because they specify the values that the searched motion sequence should approach. For example, by considering a character's in-game right foot position as a feature during the search, the system prioritizes motion that starts with the same right foot position. Similarly, by adding the in-game character's desired future right foot position as a feature, the search is steered toward selecting a motion that will move the right foot to that position. The first example is a pose-conserving feature, while the second example is a controlling feature. It is important to balance the influence of pose-conserving and controlling features to achieve an acceptable trade-off between responsiveness and smoothness. In Fig. 3, one can see how each frame of data forms a smooth trajectory in an hypothetical feature space.

Motion matching is essentially making search queries, and the design of the possible queries impacts the quality of the generated motion. It is necessary to have simple and general queries. To improve the generality of spatial features, they are encoded in a relative coordinate system based on the character's facing direction projected to the ground, which is called the character reference frame. The character reference frame is described with an affine transform ρ which can be applied to any transform as $\rho^{-1} \times A$ encoding A in the character reference frame. By applying ρ^{-1}, spatial features and pose sequences are made invariant to translations and rotations in the plane relative to the character. For example, the pose sequence and spatial features of a character walking forward in any cardinal direction are the same in the character reference frame since it is forward with respect to the character's direction. Thanks to the invariance provided by the character reference frame, it is not necessary to record a separate walking forward animation for every possible direction.

Each frame k in the database is associated with a pose and a set of numerical features. The j-th



Motion Matching: Data-Driven Character Animation Systems, Fig. 3 An hypothetical 2D query space made from the features of multiple frames of motion data and a query point. The frames form a discretized trajectory in the feature space and the distance between the query and each frame can be computed

feature at frame k is computed as $f_{j,\,k} \in \mathbb{R}$ where $j \in \{0, \ldots, J\}$ and J is the number of features. Concatenating every frame's features vertically forms the feature matrix F.

$$F = \begin{bmatrix} f_{0,0} & \cdots & f_{0,K} \\ \vdots & \ddots & \vdots \\ f_{J,0} & \cdots & f_{J,K} \end{bmatrix} \tag{3}$$

To account for the variable scales of the features (rows), the mean μ_j and standard deviation σ_j of each feature are computed, where $f_{j,k}$ is the j-th row and k-th column of the feature matrix F as shown below:

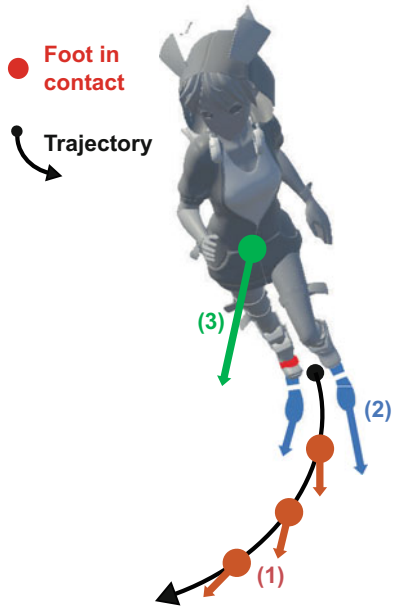
$$\mu_j = \frac{1}{K} \sum_{k=0}^{K} f_{j,k} \tag{4}$$

$$\sigma_j = \sqrt{\frac{1}{K} \sum_{k=0}^{K} \left(f_{j,k} - \mu_j\right)^2} \tag{5}$$

Each feature is also optionally tuned with a custom weight w_j yielding the final scaled feature as $d_{j,k} = \frac{w_j \times f_{j,k}}{\sigma_j}$.

Those feature are compared with a query vector $q = [d_{0,q}, d_{1,q}, \ldots, d_{J,q},]$ which is computed in real time from the game situation. Searching the best frame turns into a comparison between q and every scaled columns of F.

Holden et al. (2020) and Bergamin (2021) shared a set of spatial features found to be effective for locomotion. Figure 4 illustrates three conventional motion matching features. Firstly, steering and velocity control are achieved by matching the character reference frame positions



Motion Matching: Data-Driven Character Animation Systems, Fig. 4 An illustration of effective spatial features for locomotion extracted from frames of motion data. (1) A group of future positions of the character. (2) The positions and velocities of the feet. (3) The hip velocity. The group in (1) is made of control features, while (2) and (3) are pose-conserving features. Feet in contact with the ground are also marked for procedural adjustments

0.33, 0.66, and 1 second in the future relative to the current character reference frame. This matching compares candidate trajectories starting at every frame with the desired trajectory formed from a game-pad. Secondly, matching the character's current foot velocities and positions relative to the character reference frame maintain consistent foot placement and reduce foot sliding artifacts. Thirdly, matching the character's current hip velocity relative to the character reference frame stabilizes the character's orientation.

Search

The motion matching search is identical to finding the closest neighbor in the k-nearest neighbors algorithm (Holden 2018). The idea is straightforward; a transition cost between the query vector q and each frame's feature in the database is used to rank neighbors. Figure 3 illustrates the geometrical closeness of an hypothetical query vector with recorded features in a 2D feature space. The cost of one recorded frame is measured using Eq. 6, which calculates the squared distance with each feature vector.

$$c_k = \sum_{j=0}^{J} \left(d_{j,q} - d_{j,k}\right)^2 \tag{6}$$

In the end, the pose sequence associated with the frame with the lowest total cost $k^* = \arg\min_k c_k$ will be blended in. A variation proposed in Häfliger and Kurabayashi (2021) relies on a specific distance function per feature instead of a generic distance function, removing the need to compute the scaled features $d_{j,k}$ but instead normalizes the separate costs.

The search algorithm scales with the number of compared frames, leading to a trade-off between the amount of variation in the dataset and the retrieval speed. Fortunately, there is a lot of literature on optimizing the k-nearest neighbors algorithm to accelerate the search while guaranteeing a valid result. In most cases, only the frame with the minimum cost is relevant (closest neighbor), and it is not necessary to compute the exact score of each frame. To accelerate the search, the early out matching variation shown in Algorithm 1 can be used. This method involves skipping a candidate frame as soon as its partial cost sum exceeds the score of the current best frame.

Algorithm 1 Early out matching

Input: A reference to the motion database and the query vector

Output: The index of the pose sequence in the DB with the lowest cost, k^*

1: $d_{0,q}, d_{1,q}, \ldots, d_{J,q} \leftarrow$ *query vector*
2: $c^* \leftarrow c_0$
3: $k^* \leftarrow 0$
4: ***for*** $k = 1, 2, \ldots, K$ **do**
5: $c_k \leftarrow 0$
6: ***for*** $j = 0, 1, \ldots, J$ **do**
7: $d_{j,k} \leftarrow$ *motion database*
8: $c_k \leftarrow c_k + (d_{j,q} - d_{j,k})^2$
9: **if** $c_k > c^*$ **then**
10: *skip* to next k
11: **end if**
end for

12: **if** $c_k < c^*$ **then**
13: $k^* \leftarrow k$
14: $c^* \leftarrow c_k$
15: **end if**
end for
16: return k^*

Another conventional acceleration is achieved by pre-computing a hierarchy of bounding volumes per feature vector. The cost of the bounding volume is checked before the feature vectors inside the volume, skipping a majority of score computation when the bounds are well tuned. In practice, as hinted by the database layout in Fig. 2, only frames whose action corresponds to the current user-selected action are considered. During transitions, it is also advised to consider past actions. A mapping between actions and their corresponding frames is stored to enable this pruning of the search.

It is also possible to accelerate motion matching by tolerating some retrieval imprecision. Techniques such as quantization or dimensionality reduction applied to every $d_{j,k}$ can reduce the computational burden of the search. A dimensionality reduction technique, PCA (Pearson 1901; Hotelling 1933), diminishes the feature vector sizes by projecting them to a lower-dimension coordinate system. Consider a feature matrix $X \in \mathbb{R}^{K \times J}$ that contains K mean normalized feature vectors of J dimensions (one vector per row). PCA provides a projection matrix $W \in \mathbb{R}^{J \times J}$ composed of J eigenvectors ordered by their influence on the total variance of the projected features. A subset of the most influential columns of the projection matrix $W_L \in \mathbb{R}^{J \times L}$ where $L < J$ is extracted to project features to a lower-dimension coordinate system by applying the truncated transformation $X_{pca} = XW_L$. Despite the lousy projection, the projected features still conserve most of the variance of the non-optimized features. Furthermore, a quantization of the feature values, for example, by using a reduced number of bits, can also accelerate the speed; Büttner (2019) introduced such a scheme by encoding vectors with short codes. Finally, Holden et al. (2020) showed how deep neural networks could approximate the motion matching algorithm enabling constant inference time.

Blending

After the search, the optimal frame k^* from where to start playing back the pose sequence is obtained. However, if the new sequence is directly played, a noticeable jump in the character pose will be visible. One solution called cross-fading consists of interpolating toward the new sequence in a short period by gradually translating/rotating each bone position/rotation toward their new values. For human motion data, such interpolation produces natural transitions (Safonova and Hodgins 2005).

Assuming two sequences s^0 and s^1 of length n, each pose is merged using a *mix* function: $P_i = mix\left(P_i^0, P_i^1, \frac{i}{n}\right) \forall_i \in 0..n$, where mix applies a linear interpolation (Lerp) to each bone position and a spherical linear interpolation (Slerp) to each rotations. The factor $\frac{i}{n}$ controls the influence between the old and the new sequences, when $i = n$ only the new pose is considered. The Slerp and Lerp functions are described in Eq. 7 for positions p_0, p_1, quaternions q_0, q_1, and coefficient α.

$$\begin{aligned} Lerp(p_0, p_1, \alpha) &= (1 - \alpha) \times p_0 + \alpha \times p_1. \\ Slerp(q_0, q_1, \alpha) &= q_0 \left(q_0^{-1} q_1\right)^{\alpha}. \end{aligned} \tag{7}$$

Cross-fading is not preferred in practice, as it requires evaluating all blended sequences, which is resource intensive in scenarios where there may be more than two blended sequences. In complex games, the actual motion results from multiple procedural adjustments applied on top of the raw poses (Ilkka and Ville 2021), such as rotating the character's head toward a relevant object or enforcing that the character doesn't traverse a wall. Evaluating multiple sequences is too computationally expensive; therefore, Inertialization (Bollo 2018), which only requires the evaluation of the new sequence and often produces more natural transitions, is preferred. This technique works by interpolating between the source and target poses through an approximated smooth curve that considers the initial velocities of the source sequence joints and estimates suitable accelerations.

Procedural Adjustments

Motion matching is often limited by issues such as foot sliding due to the blending of dissimilar poses or the feet going through the ground in complex terrain. Adjusting the pose data of a found sequence to mitigate these artifacts and add other effects depends on the specific requirements of a game.

One approach to addressing issues with the feet is to mark each frame index k with two boolean values indicating whether the right or left foot is in contact with the ground. When playing a sequence in which a foot should be in contact, the system can use this information to ensure that the foot reaches the ground and does not move too much horizontally (on non-slippery surfaces). To accomplish this, the system can adjust the position of the foot to stay on top of the ground geometry beneath it. This can be achieved by performing a raycast, which involves shooting a virtual ray to detect the terrain geometry by finding the closest collisions. For a typical foot-knee-hip bone chain, the adjustment can be made by finding the knee and hip rotations that allow the foot to reach the desired location. In general, this problem of finding such rotations is known as Inverse Kinematics (Aristidou et al. 2018). There is an efficient closed-form solution for a two-joint kinematic chain in a fixed plane, and readers can refer to Holden (2017) for an intuitive derivation.

Making Queries

To be effective, the animations played back by motion matching must be of high quality and include sufficient variations to cover a wide range of gameplay scenarios. Traditionally, motion clips are recorded through motion capture, either by having the actor perform a precisely orchestrated choreography or by allowing them to move freely and randomly. Structured and unstructured motion clips can both be useful in this context. Because of the vertical symmetry of the human body, the data can be mirrored to reduce the number of necessary takes by half in well-planned sessions. However, it is difficult to anticipate and capture every possible transition, so unstructured takes can also be useful in filling in the gaps. Finally, designers can mark valid frame sequences in the data to remove duplicates, fix poor acting, and customize the system's runtime behavior.

In addition to having high-quality data, it is also important to generate query features that correspond to the recorded features, or the matches will be of poor correspondence. Pose-conserving features can be used as-is, since they are already derived from previously played back data. Control features, on the other hand, can be more challenging to craft, as they must approximate natural human locomotion while being generated from a game controller. One common approach is to simulate the evolution of a spring to generate natural and parameterized future trajectories. Holden (2021b) presents live examples and rigorous derivations of such spring simulation for games. The spring behavior can be tuned through multiple parameters to match the desired control scheme and generate appropriate queries.
